

N32G003 series

32-bit ARM® Cortex®-M0 microcontroller

User manual V1.0

Contents

1 Abbrevia	ations in the text	
1.1 List	of abbreviations for registers	
1.2 Avail	lable peripherals	
2 Memory	and bus architecture	
2.1 Syste	em architecture	
2.1.1	Bus architecture	
2.1.2	Bus address mapping	
2.1.3	Boot management	
2.2 Men	ory system	
2.2.1	FLASH specification	
2.2.2	SRAM	
2.2.3	FLASH register description	
3 Power co	ontrol (PWR)	
3.1 Gene	eral description	
3.1.1	Power supply	
3.1.2	Power supply supervisor	
3.2 Powe	er modes	
3.2.1	STOP mode	
3.2.2	PD mode	
3.3 Debu	ıg mode	
3.3.1	Low power mode debug mode support	
3.3.2	Peripheral debug support	
3.4 PWF	R registers	
3.4.1	PWR register overview	
3.4.2	Power control register (PWR_CTRL)	
3.4.3	Power control status register (PWR_CTRLSTS)	
3.4.4	Power control register 2 (PWR_CTRL2)	
3.4.5	Power control register 3 (PWR_CTRL3)	
3.4.6	Power control register 4 (PWR_CTRL4)	
3.4.7	Power control register 5 (PWR_CTRL5)	
3.4.8	Power control register 6 (PWR_CTRL6)	
3.4.9	Debug control register (DBG_CTRL)	
4 Reset an	d clock control (RCC)	
4.1 Rese	t Control Unit	
4.1.1	Power reset	
4.1.2	System reset	
4.2 Cloc	k control unit	
4.2.1	Clock Tree Diagram	

4.2.2	HSI clock	58
4.2.3	LSI clock	59
4.2.4	System clock (SYSCLK) selection	59
4.2.5	Watchdog clock	59
4.2.6	TIM6 clock	60
4.2.7	Clock output(MCO)	60
4.3 RCC	registers	60
4.3.1	RCC register overview	60
4.3.2	HSI clock control register (RCC_HSICTRL)	61
4.3.3	Clock configuration register (RCC_CFG)	62
4.3.4	Peripheral reset register (RCC_PRST)	63
4.3.5	AHB peripheral clock enable register (RCC_AHBPCLKEN)	65
4.3.6	APB peripheral clock enable register (RCC_APBPCLKEN)	66
4.3.7	Low speed clock control register (RCC_LSICTRL)	67
4.3.8	Control/status register (RCC_CTRLSTS)	68
4.3.9	Clock configuration register 2 (RCC_CFG2)	
4.3.10	EMC control register (RCC_EMCCTRL)	71
5 GPIO and	1 AFIO	72
	nary	
	nction description	
5.2.1	IO mode configuration	
5.2.2	Status after reset	
5.2.3	Individual bit setting and bit clearing	
5.2.4	External interrupt/wake-up line	
5.2.5	Alternate function	
5.2.6	I/O configuration of peripherals	
5.2.7	GPIO locking mechanism	
5.3 GPIO	registers	
5.3.1	GPIOA register overview	
5.3.2	GPIOB register overview	
5.3.3	GPIO port mode register (GPIOx_PMODE)	
5.3.4	GPIO port type register (GPIOx_POTYPE)	89
5.3.5	GPIO slew rate register (GPIOx_SR)	
5.3.6	GPIO port pull-up/pull-down register (GPIOx_PUPD)	90
5.3.7	GPIO port input data register (GPIOx_PID)	
5.3.8	GPIO port output data register (GPIOx_POD)	
5.3.9	GPIO port bit set/clear register (GPIOx_PBSC)	
5.3.10	GPIO port bit clear register (GPIOx_PBC)	
5.3.11	GPIO port lock register (GPIOx_PLOCK)	
5.3.12	GPIO alternate function low register (GPIOx_AFL)	
5.3.13	GPIO alternate function high register (GPIOx_AFH)	
5.3.14	GPIO driver strength register (GPIOx_DS)	
5.4 AFIO	registers	

5.4.1	AFIO register overview	
5.4.2	AFIO configuration register (AFIO_CFG)	
6 Interrup	ts and events	
6 1 Neste	ed vectored interrupt controller	98
6.1.1	SysTick calibration value register	
6.1.2	Interrupt and exception vectors.	
	rnal interrupt/event controller (EXTI)	
6.2.1	Introduction	
6.2.2	Main features	
6.2.3	Functional description	
6.2.4	EXTI line mapping	
6.3 EXT	I Registers	
6.3.1	EXTI register overview	
6.3.2	Interrupt mask register(EXTI_IMASK)	
6.3.3	Event mask register(EXTI_EMASK)	
6.3.4	Rising edge trigger selection register(EXTI_RT_CFG)	
6.3.5	Falling edge trigger selection register(EXTI_FT_CFG)	
6.3.6	Software interrupt enable register(EXTI_SWIE)	
6.3.7	Interrupt request pending register(EXTI_PEND)	
7 CRC cale	culation unit	
7.1 CRC	introduction	
	main features	
	function description	
	software calculation method	
7.5 CRC	registers	
7.5.1	CRC register overview	
7.5.2	CRC16 control register (CRC_CRC16CTRL)	
7.5.3	CRC16 input data register (CRC_CRC16DAT)	
7.5.4	CRC cyclic redundancy check code register (CRC_CRC16D)	
7.5.5	LRC result register (CRC_LRC)	
8 Advance	d-control timers (TIM1)	110
8 1 TIM	l introduction	
	features of TIM1	
	function description	
8.3.1	Time-base unit	
8.3.2	Counter mode	
8.3.3	Repetition counter	
8.3.4	Clock selection	
8.3.5	Capture/compare channels	
8.3.6	Input capture mode	
8.3.7	PWM input mode	

8.3.8	Forced output mode	
8.3.9	Output compare mode	
8.3.10	PWM mode	
8.3.11	One-pulse mode	
8.3.12	Clearing the OCxREF signal on an external event	
8.3.13	Complementary outputs with dead-time insertion	
8.3.14	Break function	
8.3.15	Debug mode	
8.3.16	TIMx and external trigger synchronization	
8.3.17	Timer synchronization	
8.3.18	6-step PWM generation	
8.4 TIM	x register description(x=1)	
8.4.1	Register Overview	
8.4.2	Control register 1 (TIMx_CTRL1)	
8.4.3	Control register 2 (TIMx_CTRL2)	147
8.4.4	Slave mode control register (TIMx_SMCTRL)	
8.4.5	Interrupt enable registers (TIMx_DINTEN)	
8.4.6	Status registers (TIMx_STS)	
8.4.7	Event generation registers (TIMx_EVTGEN)	
8.4.8	Capture/compare mode register 1 (TIMx_CCMOD1)	
8.4.9	Capture/compare mode register 2 (TIMx_CCMOD2)	
8.4.10	Capture/compare enable registers (TIMx_CCEN)	
8.4.11	Counters (TIMx_CNT)	
8.4.12	Prescaler (TIMx_PSC)	
8.4.13	Auto-reload register (TIMx_AR)	
8.4.14	Repeat count registers (TIMx_REPCNT)	
8.4.15	Capture/compare register 1 (TIMx_CCDAT1)	
8.4.16	Capture/compare register 2 (TIMx_CCDAT2)	
8.4.17	Capture/compare register 3 (TIMx_CCDAT3)	
8.4.18	Capture/compare register 4 (TIMx_CCDAT4)	
8.4.19	Break and Dead-time registers (TIMx_BKDT)	
8.4.20	Capture/compare mode registers 3(TIMx_CCMOD3)	
8.4.21	Capture/compare register 5 (TIMx_CCDAT5)	
9 General-j	purpose timers (TIM3)	
9.1 Gene	ral-purpose timers introduction	
9.2 Main	features of General-purpose timers	
9.3 Gene	ral-purpose timer description	
9.3.1	Time-base unit	
9.3.2	Counter mode	
9.3.3	Clock selection	176
9.3.4	Capture/compare channels	
9.3.5	Input capture mode	
9.3.6	PWM input mode	

9.3.7	Forced output mode	
9.3.8	Output compare mode	
9.3.9	PWM mode	
9.3.10	One-pulse mode	
9.3.11	Clearing the OCxREF signal on an external event	
9.3.12	Debug mode	
9.3.13	TIMx and external trigger synchronization	
9.3.14	Timer synchronization	
9.4 TIMx	register description(x=3)	
9.4.1	Register Overview	
9.4.2	Control register 1 (TIMx_CTRL1)	
9.4.3	Control register 2 (TIMx_CTRL2)	
9.4.4	Slave mode control register (TIMx_SMCTRL)	
9.4.5	Interrupt enable registers (TIMx_DINTEN)	
9.4.6	Status registers (TIMx_STS)	
9.4.7	Event generation registers (TIMx_EVTGEN)	
9.4.8	Capture/compare mode register 1 (TIMx_CCMOD1)	
9.4.9	Capture/compare enable registers (TIMx_CCEN)	
9.4.10	Counters (TIMx_CNT)	
9.4.11	Prescaler (TIMx_PSC)	
9.4.12	Auto-reload register (TIMx_AR)	
9.4.13	Capture/compare register 1 (TIMx_CCDAT1)	
9.4.14	Capture/compare register 2 (TIMx_CCDAT2)	211
9.4.14	Capture/compare register 2 (TIWA_CCDAT2)

11.2 IWD0	G main features	
11.3 IWD0	G function description	
11.3.1	Register access protection	
11.3.2	Debug mode	
11.3.3	Low power consumption	
11.4 User 1	Interface	
11.4.1	Operate Flow	
11.4.2	IWDG configuration flow	
11.5 IWD0	G registers	
11.5.1	IWDG register map	
11.5.2	IWDG Key register (IWDG_KEY)	
11.5.3	IWDG Pre-Scaler register (IWDG_PREDIV)	
11.5.4	IWDG Reload register (IWDG_RELV)	
11.5.5	IWDG Status register (IWDG_STS)	
11.5.6	IWDG Freeze register (IWDG_FREEZE)	
12 Analog to	digital conversion (ADC)	
12.1 ADC	introduction	
	Features	
	function description	
12.3.1	ADC clock	
12.3.2	ADC switch control	
12.3.3	Channel selection	
12.3.4	Internal channel	
12.3.5	Single conversion mode	
12.3.6	Continuous conversion mode	
12.3.7	Timing diagram	
12.3.8	Analog watchdog	
12.3.9	Scan mode	
12.4 Data a	aligned	
	ammable channel sampling time	
-	nally triggered conversion	
	interrupt	
12.8 ADC	registers	
12.8.1	ADC registers	
12.8.2	ADC status register (ADC_STS)	
12.8.3	ADC control register 1 (ADC_CTRL1)	
12.8.4	ADC control register 2 (ADC_CTRL2)	
12.8.5	ADC control register 3 (ADC_CTRL3)	
12.8.6	ADC sampling time register (ADC_ SAMPT)	
12.8.7	ADC watchdog high threshold register (ADC_WDGHIGH)	
12.8.8	ADC watchdog low threshold register (ADC_WDGLOW)	
12.8.9	ADC regular data register x (ADC_DATx) (x= 04)	

3 Compara	tor (COMP)	
13.1 COM	P system connection block diagram	
13.2 COM	P features	
13.3 COM	P configuration process	
13.4 COM	P working mode	
13.4.1	Independent comparator	
13.5 Comp	parator interconnection	
-	upt	
	P registers	
13.7.1	COMP registers	
13.7.2	COMP interrupt enable register (COMP_INTEN)	
13.7.3	COMP interrupt status register (COMP_INTSTS)	
13.7.4	COMP lock register (COMP_LOCK)	
13.7.5	COMP control register (COMP_CTRL)	
13.7.6	COMP filter control register (COMP_FILC)	
13.7.7	COMP filter clock register (COMP_FILP)	
4 Inter-inte	grated circuit bus(I ² C)	
14.1 Introd	luction	
14.2 Main	features	
14.3 Funct	ion description	
14.3.1	SDA and SCL line control	
14.3.2	Software communication process	
14.3.3	Error conditions description	
14.3.4	Packet error check	
14.3.5	Noise filter	
14.4 Interr	upt request	
14.5 I2C re	egisters	
14.5.1	I2C register overview	
14.5.2	I2C Control register 1 (I2C_CTRL1)	
14.5.3	I2C Control register 2 (I2C_CTRL2)	
14.5.4	I2C Own address register 1 (I2C_OADDR1)	
14.5.5	I2C Own address register 2 (I2C_OADDR2)	
14.5.6	I2C Data register (I2C_DAT)	
14.5.7	I2C Status register 1 (I2C_STS1)	
14.5.8	I2C Status register 2 (I2C_STS2)	
14.5.9	I2C Clock control register (I2C_CLKCTRL)	
14.5.10	I2C Rise time register (I2C_TMRISE)	
14.5.11	I2C Filter control register (I2C_GFLTRCTRL)	
14.5.12	I2C master receive byte register (I2C_BYTENUM)	
	asynchronous receiver transmitter (UART)	
	luction	

15.2 Main	features	
15.3 Funct	tional block diagram	
15.4 Funct	tion description	
15.4.1	UART frame format	
15.4.2	Transmitter	
15.4.3	Receiver	
15.4.4	Generation of fractional baud rate	
15.4.5	Receiver's tolerance clock deviation	
15.4.6	Parity control	
15.4.7	Multiprocessor communication	
15.4.8	Single-line half-duplex communication	
15.5 Interr	rupt request	
15.6 UAR	T mode configuration	
15.7 UAR	T registers	
15.7.1	UART register map	
15.7.2	UART status register (UART_STS)	
15.7.3	UART data register (UART_DAT)	
15.7.4	UART baud rate configuration register (UART_BRCF)	
15.7.5	UART control register 1(UART_CTRL1)	
15.7.6	UART control register 2(UART_CTRL2)	
15.7.7	UART control register 3(UART_CTRL3)	
16 Serial per	ripheral interface (SPI)	
16.1 SPI ii	ntroduction	
	nain features	
	unction description	
16.3.1	General description	
16.3.2	SPI work mode	
16.3.3	Status flag	
16.3.4	Turn off the SPI	
16.3.5	Error flag	
16.3.6	SPI interrupt	
16.4 SPI r	egister	
16.4.1	SPI register overview	
16.4.2	SPI control register 1 (SPI_CTRL1)	
16.4.3	SPI control register 2 (SPI_CTRL2)	
16.4.4	SPI status register (SPI_STS)	
16.4.5	SPI data register (SPI_DAT)

1 Abbreviations in the text

1.1 List of abbreviations for registers

The following abbreviations are used in register descriptions:

read/write(rw)	Software can read and write these bits.
read-only(r)	Software can only read these bits.
write-only(w)	Software can only write this bit, and reading this bit will return the reset
	value.
read/clear(rc_w1)	Software can read this bit or clear it by writing' 1', and writing' 0' has no
	effect on this bit.
read/clear(rc_w0)	Software can read this bit or clear it by writing' 0', and writing' 1' has no
	effect on this bit.
read/clear by read(rc_r)	Software can read this bit. Reading this bit will automatically clear it to' 0'.
	Writing' 0' has no effect on this bit.
read/set(rs)	Software can read or set this bit. Writing' 0' has no effect on this bit.
read-only write trigger(rt_w)	Software can read this bit and write' 0' or' 1' to trigger an event, but it has no
	effect on this bit value.
toggle(t)	Software can only flip this bit by writing' 1', and writing' 0' has no effect on
	this bit.
Reserved(Res.)	Reserved bit, must be kept at reset value.

1.2 Available peripherals

For all models of N32G003 microcontroller series, the existence and number of a peripheral, please refer to the data sheet of the corresponding model.

2 Memory and bus architecture

2.1 System architecture

2.1.1 **Bus architecture**

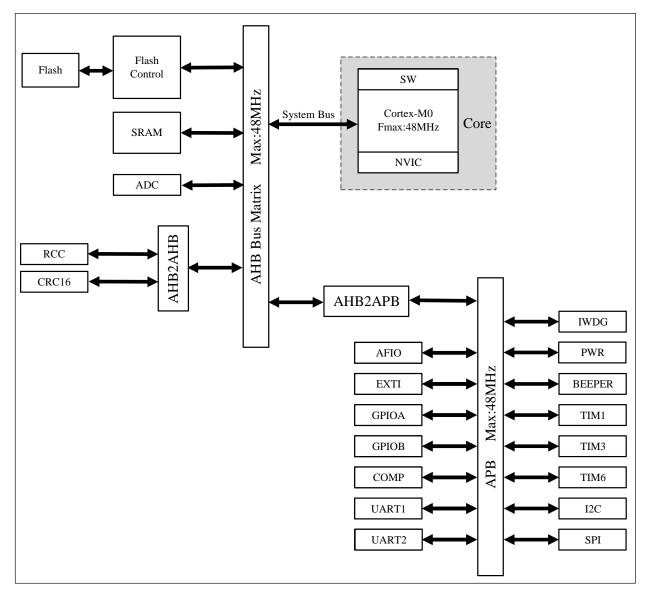

The main system consists of the following parts:

- One master device:
 - ♦ Cortex®-M0 core
- Five slave devices:
 - ♦ Internal flash memory
 - ♦ Internal SRAM
 - ♦ AHB2AHB bridge, which connects AHB modules
 - ♦ ADC
 - ♦ AHB2APB bridge, which connects APB modules

The system bus architecture is shown as in Figure 2-1:

Figure 2-1 Bus architecture

- CPU System bus: Connects to the Cortex[®]-M0 kernel bus to bus matrix, used for instruction pre-fetch, data load (constant load and debug access) and AHB/APB peripheral access.
- The bus matrix coordinates access arbitration the kernel system bus. The bus matrix consists of only 1 driver components (CPU system bus) and five slave components (flash memory interface, SRAM, ADC, AHB and APB system bus). Some AHB peripherals are connected to system bus through a bus matrix.
- The system consists of 1 AHB2APB Bridges. APB contains 16 APB peripherals and the maximum speed of PCLK is 48MHz.

2.1.2 Bus address mapping

The address mapping includes all AHB peripherals, APB peripherals, Flash, SRAM, System Memory, etc. The specific mapping is as follows:

Figure 2-2 Bus address map

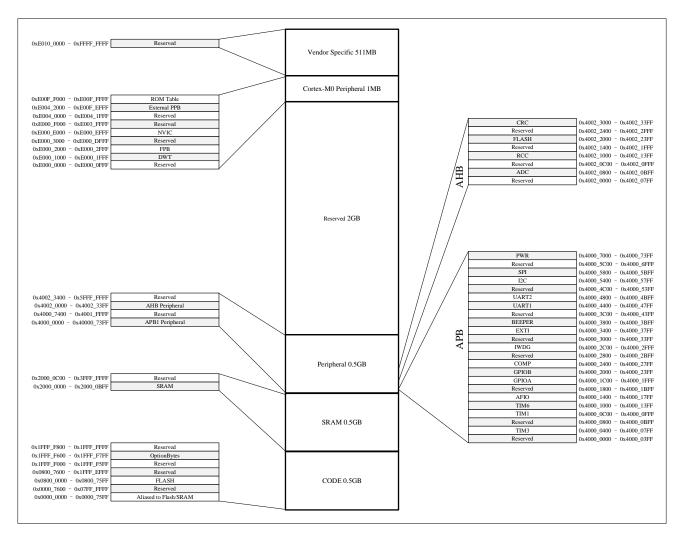

Table 2-1 List of peripheral register addresses

Address range	Peripherals	Bus		
0x4002_3400 - 0x5FFF_FFFF	Reserved			
0x4002_3000 - 0x4002_33FF	CRC			
0x4002_2400 - 0x4002_2FFF	Reserved			
0x4002_2000 - 0x4002_23FF	FLASH

0x4000_2000 - 0x4000_23FF	GPIOB	
0x4000_1C00 - 0x4000_1FFF	GPIOA	
0x4000_1800 - 0x4000_1BFF	Reserved	
0x4000_1400 - 0x4000_17FF	AFIO	
0x4000_1000 - 0x4000_13FF	TIM6	
0x4000_0C00 - 0x4000_0FFF	TIM1	
0x4000_0800 - 0x4000_0BFF	Reserved	
0x4000_0400 - 0x4000_07FF	TIM3	
0x4000_0000 - 0x4000_03FF	Reserved	

2.1.3 **Boot management**

2.1.3.1 Boot address

During system startup, after a startup delay, the CPU gets the address at the top of the stack from address 0x0000_0000 and executes the code from the reset vector address indicated by address 0x0000_0004.Because of the Cortex[®]-M0 always gets the stack top pointer and reset vector from addresses 0x0000_0000 and 0x0000_0004, so boot is only suitable for starting from the CODE area, and address remapping is designed for boot space.

- Boot from Main Flash memory:
 - Main flash memory is mapped to the boot space (0x0000_0000);
 - ♦ Main flash memory is accessible in two address areas, 0x0000_0000 or 0x0800_0000;

2.2 Memory system

The program memory, data memory, registers and I/O ports are organized in the same 4GB linear address space. Data bytes are stored in the memory in little endian format. The lowest address byte in a word is regarded as the least significant byte of the word, while the highest address byte is the most significant byte. The specifications of program memory and data memory are as follows.

2.2.1 **FLASH specification**

Flash consists of the main memory area and the information area, which are described separately below:

- The maximum size of the main memory area is 29.5KB, also known as primary flash memory, and contains 59 pages for the storage and running of user programs, as well as data memory.
- The information area is 2KB, containing 4 pages, which is composed of the system configuration area (1.5KB), and option byte area (0.5KB):
 - The system configuration area is 1.5KB and contains three pages.
 - OptionByte area is 0.5KB, including 1 Page, the effective space is 16B, user programs can read and write erase.

2.2.1.1 Flash memory module organization

Bus address space is allocated to the main storage area and the information area.

Memory area	Page name	Address range	Size
	Page 0	0x0800_0000 - 0x0800_01FF	0.5 KB
	Page 1	0x0800_0200 - 0x0800_03FF	0.5 KB
The main memory	Page 2	0x0800_0400 - 0x0800_05FF	0.5 KB
area	:	:	÷
	Page 58	0x0800_7400 - 0x0800_75FF	0.5 KB
Information and	System configuration area	0x1FFF_F000 – 0x1FFF_F5FF	1.5 KB
Information area	Option byte area	0x1FFF_F600 - 0x1FFF_F60F	16B
	FLASH_AC	0x4002_2000 - 0x4002_2003	4B
	FLASH_KEY	0x4002_2004 - 0x4002_2007	4B
	FLASH_OPTKEY	0x4002_2008 - 0x4002_200B	4B
	FLASH_STS	0x4002_200C - 0x4002_200F	4B
Memory area	FLASH_CTRL	0x4002_2010 - 0x4002_2013	4B
interface register	FLASH_ADD	0x4002_2014 - 0x4002_2017	4B
	Reserved	0x4002_2018 - 0x4002_201B	4B
	FLASH_OB	0x4002_201C - 0x4002_201F	4B
	FLASH_USER2	0x4002_2020 - 0x4002_2023	4B
	FLASH_VTOR	0x4002_2024 - 0x4002_2027	4B

Table 2-2 Flash bus address list

Flash memory is organized into 32-bit wide memory cells that can hold code and data constants.

The information area is divided into two parts:

- System configuration area, which contains basic chip information.
- Option byte area.

Writing to main memory and information block is managed by embedded flash programming/erasing controller.

There is two ways to protect flash memory from illegal access (read, write and erase):

- Permissions protect
- Readout protection (RDP)

When performing flash programming operations (write or erase), the internal RC oscillator (HSI) must be turned on.

When the flash memory write operation is executed, any read operation to the flash memory will lock the bus, and the read operation can only be carried out correctly after the write operation is completed. That is, when writing or erasing, cannot have any read access to the code or data.

The internal RC oscillator (HSI) must be turned on when the flash memory is programmed (written or erased).

Note: In the low power consumption mode, all flash memory operations are suspended.

2.2.1.2 Read and write operation

The Flash operation only supports 32-bit operation, and the Flash should be erased before the write operation, and the minimum block size for erasing is one Page 0.5KB. Write operation is divided into erasing and programming phases.

When reading Flash, the number of waiting cycles for reading can be configured by the register. When using, it needs to be calculated in combination with the clock frequency of SYSCLK interface. For example, when SYSCLK <= 24MHz, the minimum number of waiting periods is 0; When 24MHz< SYSCLK <= 48MHz, the minimum number of waiting periods is 1.

Note: Enable prefetch buffer whether number of wait periods is not zero can improve overall efficiency.

2.2.1.3 Unlock Flash

After reset, the Flash module is protected and cannot be written into the FLASH_CTRL register to prevent accidental operation of Flash due to electrical interference and other reasons. By writing a specific sequence of key values into the FLASH_KEY register, you can open the operation authority of the FLASH_CTRL register. The specific sequence is: Firstly, writing KEY1 = 0x45670123 in the FLASH_KEY register. Secondly, write KEY2 = 0xCDEF89AB in the FLASH_KEY register.

If there is an error in sequence or key value, a bus error will be returned and the FLASH_CTRL register will be locked until the next reset. The software can check whether the Flash has been unlocked by looking at the FLASH_CTRL.LOCK bit. If normal lock setting is needed, it can be realized by setting the FLASH_CTRL.LOCK bit to 1 by software. After that, you can unlock the Flash by writing the correct key value series in FLASH_KEY.

2.2.1.4 Erase and program

2.2.1.4.1 Main memory area erased

The main memory area can be erased page by page or whole.

Page Erase

Page Erase process(when FLASH_OB.BOOT_LOCK = 1, then first 3K not erase):

- Check the FLASH_STS.BUSY bit to confirm that there are no other flash operations in progress;
- Set the FLASH_CTRL.PER bit to '1';
- Select the page to be erased with the FLASH_ADD register;
- Set the FLASH_CTRL.START bit to '1';
- Wait for the FLASH_STS.BUSY bit to change to '0';

Read out the erased page and verify it.

Mass Erase

Mass Erase process:

- Check the FLASH_STS.BUSY bit to confirm that there are no other flash operations in progress;
- Set the FLASH_CTRL.MER bit to '1';
- Set the FLASH_CTRL.START bit to '1';
- Wait for the FLASH_STS.BUSY bit to change to '0';
- Read out all pages and verify.

2.2.1.4.2 Main memory area programming

The main memory area can be programmed with 32 bits at a time. When the FLASH_CTRL.PG bit is '1', writing a word in a flash address will start programming once; Writing any half word of data will result in a bus error. During the programming process (the FLASH_STS.BUSY bit is '1'), any operation of reading or writing the flash memory will cause the CPU to pause until the end of the flash programming.

Main memory programming process:

- Check the FLASH_STS.BUSY bit to confirm that there are no other flash operations in progress;
- Set the FLASH_CTRL.PG bit to '1';
- Write the word to be programmed at the specified address;
- Wait for the FLASH_STS.BUSY bit to change to '0';
- Read the written address and verify the data.

Note: When the FLASH_STS.BUSY bit is '1', you cannot write to any register.

2.2.1.4.3 Option byte erase and programming

The option byte area is programmed differently from the main storage area. The number of option bytes is only 8 bytes (2 bytes for read protection, 4 byte for configuration options, and 2 bytes for user data memory). After unlocking the Flash, you must write KEY1 and KEY2 respectively (see section 2.2.1.3) to the FLASH_OPTKEY register, and then set the FLASH_CTRL.OPTWE bit to '1'. At this time, the option byte area can be programmed: set the FLASH_CTRL.OPTPG bit to '1' and then write the word to the specified address.

When programming the word in the option byte area, use the low byte in the half-word and automatically calculate the high byte (the high byte is the complement of the low byte), and start the programming operation, which will ensure that the option byte and its complement are always correct.

Option byte erase process:

- Check the FLASH_STS.BUSY bit to confirm that there are no other flash operations in progress;
- Unlock the FLASH_CTRL.OPTWE bit;
- Set the FLASH_CTRL.OPTER bit to '1';
- Set the FLASH_CTRL.START bit to '1';

Nation 🚯

- Wait for the FLASH_STS.BUSY bit to change to '0';
- Read the erased option byte and verify it.

Option byte area programming process:

- Check the FLASH_STS.BUSY bit to confirm that there are no other flash operations in progress;
- Unlock the FLASH_CTRL.OPTWE bit;
- Set the FLASH_CTRL.OPTPG bit to '1';
- Writing the word to be programmed to the specified address;
- Wait for the FLASH_STS.BUSY bit to change to '0';
- Read the written address and verify the data.

2.2.1.5 Instruction prefetching

The instruction prefetch function of Flash module supports the prefetch Buffer of 8B. Through instruction prefetching, the instruction execution efficiency of CPU can be improved. The instruction prefetch function can be configured to be enabled or disabled through the register, and it is enabled by default.

2.2.1.6 **Option byte**

Option byte blocks are used to configure read protection, software/hardware watchdog, and reset options when the system is in power-off or shutdown mode. In addition, bus address space is allocated for read/write access. They consist of 8 option bytes: 2 bytes for read protection, 4 byte for configuration options, and 2 bytes defined by the user, which need to be written across the bus. The option byte block also contains the inverse codes corresponding to the 8 option bytes, which are automatically calculated by the hardware when the bus writes the option bytes, written to Flash, and used for verification when the option bytes are read.

By default, option byte blocks are always readable and write-protected. To write to the option byte block (program/erase), first unlock the flash, and then unlock the option byte: write the correct sequence of key values in OPTKEY (KEY1 = 0x45670123, KEY2 = 0xCDEF89AB), and then write to the option byte block will be allowed. If the order is wrong or the key value is wrong, the bus error is returned and the option bytes are locked until the next reset. To properly set the lock, write the OPTWE bit 0 in the FLASH_CTRL register by software, and then unlock the option bytes by writing the correct key series to the FLASH_OPTKEY.

After each system reset, the option byte data is read from the option byte block of Flash and saved in the option byte register (FLASH_OB/FLASH_USER) with read-only properties. The option byte inverse data, read together, is used to verify that the option byte data is correct, and if it does not match, an option byte error flag (FLASH_OB.OBERR) is generated. When an option byte error occurs, the corresponding option byte is forced to 0xFF.If both the optional byte and its inverse code are 0xFF (the erased state), the above verification steps are skipped and no verification is required.

Table 2-3 Option byte list

Address	[31:24] Corresponding complement code	[23:16] Option byte	[15:8] Corresponding complement code	[7:0] Option byte
0x1FFF_F600	nUSER	USER	nRDP1	RDP1
0x1FFF_F604	nData1	Data1	nData0	Data0
0x1FFF_F608	nUSER3	USER3	nUSER2	USER2
0x1FFF_F60C	nUSER4	USER4	nRDP2	RDP2

- Configuration option: USER
 - ♦ USER[7:5]: Reserved;
 - USER[4]: NRST_PA0 configuration option, which can be queried by FLASH_OB[6]
 - 0: PA0 as a normal GPIO pin
 - 1: PA0 as NRST pin
 - USER[3]: BOOT_LOCK configuration option, which can be queried by FLASH_OB[5]
 - 0: Flash first 3KB is not locked
 - 1: Flash first 3KB is locked
 - USER[2]: nRST_PD configuration option, which can be queried through FLASH_OB[4]
 - 0: A reset occurs when PD mode is entered
 - 1: No reset occurs when entering PD mode
 - USER[1]: nRST_STOP configuration option, which can be queried through FLASH_OB[3]
 - 0: A reset occurs when entering STOP mode
 - 1: No reset occurs when entering the STOP mode
 - USER[0]: WDG_SW configuration option, which can be queried by FLASH_OB[2]
 - 0: Hardware watchdog
 - 1: Software watchdog
- Two bytes of user data: Datax
 - Data1 (stored in FLASH_OB[25:18]);
 - Data0 (stored in FLASH_OB[17:10]);
- Configuration options bytes:
 - USER2[7:0]: LVR filter counter control, which can be queried through FLASH_USER[7:0]
 - USER3[3:0]: LVR power on level configure, which can be queried through FLASH_USER[11:8]
 - USER3[4]: LVR enable, which can be queried through FLASH_USER[12]
 - USER3[5]: LVR filter enable, which can be queried through FLASH_USER[13]

- USER3[6]: LVR reset enable, which can be queried through FLASH_USER[14]
- USER4[7:0]: Power on delay reset control, , which can be queried through FLASH_USER[23:16]

Note: When USER and nUSER are both 0xFF, it is the erased state, the function of the corresponding bit is invalid, and it needs to be programmed to be in the inverse code state to take effect

- Read protection L1 level option byte: RDP1
 - Protect code stored in flash memory;
 - When the correct value is written, writing to the flash memory via SWD is disallowed;
 - The result of whether RDP1 is enabled can be queried by running FLASH_OB[1].
- Read protection L2 level option byte: RDP2
 - Add protection function on the basis of L1. For details, see 2.2.1.9 Read Protection.
 - The result of whether RDP2 is enabled can be queried by running FLASH_OB[31];

2.2.1.7 Read protection

The user code in flash can be protected from illegal reading by setting read protection. Read protection is set by configuring RDP bytes in the option byte block. Three different read protection levels can be configured, as shown in the following Table

Table 2-4 Read protection configuration list

Read protection status	RDP1	nRDP1	nRDP2	RDP2
L1 level	0xFF	0xFF	$RDP2! = 0xCC \parallel nRDP2! = 0x33$	
L0 level	0xA5	0x5A	$RDP2! = 0xCC \parallel nRDP2! = 0x33$	
L2 level	0xXX	0xXX	0x33	0xXX
L1 level	None of the preceding three configurations			

[■] L0 level:

- ♦ In the unprotected state, the corresponding (RDP1 = 0xA5&NRDP1 = 0x5A) && (RDP2 != 0xCC | nRDP2 != 0 x33);
- Main memory and option byte blocks can be read arbitrarily
- Can be rewritten to L1 or L2 level
- L1 level:
 - The corresponding ~(((RDP1 = 0x5&nrdP1 = 0x5A) && (RDP2 != 0xCC | nRDP2 != 0 x33) || (RDP2 = 0 XCC & nRDP2 = 0 x33));
 - Can rewrite for L2 or level of L0, when change the form of the option bytes have been read to protect unprotected L0 level will automatically be erased all the main memory area, execution process is as follows: (erase the option byte block does not lead to the entire automatically erase operation, because of erasing the result is 0xFF, equivalent to a still in a state of L1 level of protection)
 - Write the correct sequence of keys to the OPTKEY unlock option byte area;

- The bus initiates the command to erase the entire option byte area (Page erase);
- Bus write read protection option byte 0xA5;
- Internal automatic erasure of all main memory areas;
- Internally write 0xA5 to read protection option bytes;
- System reset (such as software reset, etc.), option byte blocks (including the new RDP value 0xA5) will be reloaded into the system, and read protection will be removed;
- All functions of loading and executing code into the built-in SRAM via SWD are still valid, and can also be enabled from the built-in SRAM via SWD. This function can be used to remove read protection.
- L2 level:
 - The L2 level is achieved by configuring another option byte RDP2, regardless of the value of RDP1, as long as (RDP2 = 0xCC & nRDP2 = 0x33) the LEVEL is L2.
 - The protection level cannot be changed (irreversible).
 - Features are at L1 level except that option byte write/page erase and SWD is disabled.

2.2.1.8 **Permission Protection**

- Flash main memory permissions:
 - ◆ At the L0 level: all main memory areas can be read. When FLASH_OB.BOOT_LOCK = 0, then first 3K byte can write and erase; when FLASH_OB.BOOT_LOCK = 1, then first 3K byte can not write and erase.
 - At the L1/2 level:
 - The first 3K byte read-only, other content access is allowed (W/R/PE) when code execution in FLASH/SRAM;
 - SWD disable access to FLASH/SRAM
 - When the L1 level is changed to L0, all Flash main memory areas are automatically erased.
- Flash options byte area permissions:
 - At the L0/L1 level, access is allowed (W/R/PE).
 - L2 level: Read-only access to flash option bytes is allowed except for debugging mode.
- Flash system configuration area
 - after seal, read-only

Table 2-5 Flash read-write-erase permission control table

protect	Boot mode	Flash		Changing a
protect level	Perform user Access area	Flash/SRAM	SWD	Changing a Protection Level
L0	Flash main memory area first 3KB	Read-Write-Erase	Read-Write-Erase	Change to L1 or L2 is
Level	FLASH_OB.BOOT_LOCK = 0	Reau-wille-Erase	Reau-wille-Erase	allowed

	Flash main memory area first 3KB FLASH_OB.BOOT_LOCK = 1	Only read	Only read	
	After flash main memory area first 3KB	Read-Write-Erase	Read-Write-Erase	
	Flash main memory area mass erase ⁽¹⁾	Allow	Allow	
	Flash option byte area	Read-Write-Erase	Read-Write-Erase	
	System configuration area	Only read	Only read	
	SRAM (All)	Read-Write	Read-Write	
	Flash main memory area first 3KB FLASH_OB.BOOT_LOCK = 0	Only read		
	Flash main memory area first 3KB FLASH_OB.BOOT_LOCK = 1	Only read	Forbid	Change to L0 or L2 is allowed.
L1	After flash main memory area first 3KB	Read-Write-Erase		When changed to L0,
Level	Flash main memory area mass erase ⁽¹⁾	Allow	Forbid	the main memory area is automatically
	Flash option byte area	Read-Write-Erase	Read-Write-Erase	erased
	System configuration area	Only read	Only read	crased
	SRAM (All)	Read-Write	Forbid	
	Flash main memory area first 3KB FLASH_OB.BOOT_LOCK = 0	Only read		
	Flash main memory area first 3KB FLASH_OB.BOOT_LOCK = 1	Only read		
L2	After flash main memory area first 3KB	Read-Write-Erase	Forbid	No modification is
Level	Flash main memory area mass erase ⁽¹⁾	Allow		allowed
	Flash option byte area	Only read		
	System configuration area	Only read		
	SRAM (All)	Read-Write		

Note:

1. Mean mass erase, when FLASH_OB.BOOT_LOCK = 1, then first 3K not erase.

2.2.2 **SRAM**

SRAM is mainly used for code running, storing variables and data or stacks during program execution, with a maximum capacity of 3KB.

SRAM supports byte, half word, word read and write access.

SRAM supports code running and can run programs at full speed in SRAM. The maximum address range of SRAM is 0x2000 0000 to 0x2000 0BFF.

SRAM cannot hold data in PD mode; Data in Stop mode can be maintained.

The main features are as follows:

- The maximum total capacity is 3KB
- Support byte/half word/word reading and writing

- CPU access
- The CPU BUS can remap to SRAM to run the program at full speed

2.2.3 FLASH register description

These peripheral registers must be operated as words (32 bits).

2.2.3.1 FLASH register overview

Table 2-6 FLASH register overview

Bit field	Name	Description
31:6	Reserved	Reserved, the reset value must be maintained.
5	PRFTBFS	Pre-fetch buffer status
		This bit indicates the state of the pre-fetch buffer
		0: The pre-fetch buffer is disabled.
		1: The pre-fetch buffer is enabled.
4	PRFTBFE	Pre-fetch buffer is enabled
		0: Disables the pre-fetch buffer.
		1: Enables the pre-fetch buffer.
3:2	Reserved	Reserved, the reset value must be maintained
1:0	LATENCY	Time delay
		These bits represent the ratio of the SYSCLK (system clock) cycle to the flash access
		time
		00: Zero periodic delay, when $0 < SYSCLK \le 24MHz$
		01: A periodic delay, when $24MHz < SYSCLK \le 48MHz$
		Others: Reserved

2.2.3.3 FLASH key register (FLASH_KEY)

Address offset: 0x04

Reset value: 0xXXXX XXXX

31		 	 	 	-			 	 16
	I			FKEY	[31:16]		I	 	
	1			·	w		1		
15	-	 	 	 				 	 0
				FKEY	[15:0]		1		
	1				w				

Bit field	Name	Description
31:0	FKEY	Used to unlock the FLASH_CTRL.LOCK bit.

2.2.3.4 FLASH OPTKEY register (FLASH_OPTKEY)

Address offset: 0x08

Reset value: 0xXXXX XXXX

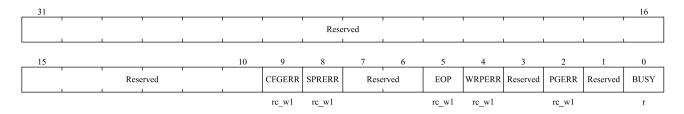

31										 		 	16
	I	1	I	I			OPTKE	Y[31:16]	I			 ı ı	
	1	1	1	1	I	LI				<u> </u>	L	II

	1	1	1	1	1		OPTKE	Y[15:0]					
							v	v					

Bit field	Name	Description
31:0	OPTKEY	Used to unlock the FLASH_CTRL.OPTWE bit.

2.2.3.5 FLASH status register (FLASH_STS)

Address offset: 0x0C

Reset value: 0x0000 0000

Bit field	Name	Description
31:10	Reserved	Reserved, the reset value must be maintained
9	CFGERR	Flash iniaial configuration error.
		Whether the Flash iniaial configuration value read out in the config is consistent with
		calibration value.
		0: Right
		1: Error
8	SPRERR	Spccial Pattern read error
		Whether the Spccial Pattern value read out in the config is consistent with calibration
		value.
		0: Right
		1: Error
7:6	Reserved	Reserved, the reset value must be maintained
5	EOP	End of the operation
		When the flash operation (programming/erasing) is complete, the hardware sets this
		to '1' and writing '1' clears this state.
		Note: EOP status is set for each successful programming or erasure.
4	WRPERR	Write protection error
		When attempting to program a write protected flash address, hardware sets this to '1'
		and writing '1' clears this state.
3	Reserved	Reserved, the reset value must be maintained
2	PGERR	Programming errors
		When trying to program to an address whose content is not '0xFFFF_FFFF', the
		hardware sets this to '1'. Writing '1' clears this state.

Bit field	Name	Description
		Note: Before programming, the FLASH_CTRL.START bit must be cleared.
1	Reserved	Reserved, the reset value must be maintained
0	BUSY	Busy
		This bit indicates that a flash operation is in progress. This bit is set to '1' at the start of
		the flash operation; This bit is cleared to '0' at the end of the operation or when an
		error occurs.

2.2.3.6 FLASH control register (FLASH_CTRL)

Address offset: 0x10

Reset value: 0x0000 0080

31															16
			I	1			Rese	erved	I			1	I		
	1	l	1	I			1	1	1			I			
15		13	12	11	10	9	8	7	6	5	4	3	2	1	0
	Reserved		EOPITE	Reserved	ERRITE	OPTWE	MMER	LOCK	START	OPTER	OPTPG	Reserved	MER	PER	PG
			rw		rw	rw	rw	rw	rw	rw	rw		rw	rw	rw

Bit field	Name	Description
31:13	Reserved	Reserved, the reset value must be maintained
12	EOPITE	Allow operation completion interrupt.
		This bit allows an interrupt to be generated when the FLASH_STS.EOP bit becomes '1'.
		0: Forbid interruption.
		1: Interrupts are allowed.
11	Reserved	Reserved, the reset value must be maintained
10	ERRITE	Allow error status to be interrupted
		This bit allows interrupts in the event of Flash errors (when
		FLASH_STS.PGERR/FLASH_STS.WRPERR is set to '1').
		0: Forbid interruption.
		1: Interrupts are allowed.
9	OPTWE	Allows option bytes to be written
		When the bit is '1', programmatic manipulation of the option byte is allowed. When the
		correct key sequence is written to the FLASH_OPTKEY register, the bit is set to '1'.
		Software can clear this bit.
8	MMER	Erase main memory area.
		0: None
		1: Erase main memory area first 48 page
7	LOCK	Lock
		This bit can only be written as '1'. When the bit is '1', Flash and FLASH_CTRL are locked.
		Hardware clears this bit to '0' after detecting a correct unlock sequence.
		After an unsuccessful unlock operation, this bit cannot be changed until the next system
		reset.
6	START	Start

Bit field	Name	Description
		An erase operation is triggered when the bit is '1'. This bit can only be set by software to '1'
		and cleared to '0' when FLASH_STS.BUSY changes to '1'.
5	OPTER	Erase option bytes
		0: Disable option bytes erase mode.
		1: Enable option bytes erase mode.
4	OPTPG	Program option bytes
		0: Disable option bytes program mode.
		1: Enable option bytes program mode.
3	Reserved	Reserved, the reset value must be maintained.
2	MER	Mass erase.
		Erase main memory area all pages.
		0: Disable mass erase mode.
		1: Enable mass erase mode.
1	PER	Page erase
		0: Disable mass erase mode.
		1: Enable mass erase mode.
0	PG	Program
		0: Disable Program mode.
		1: Enable Program mode.

Note: Please refer to Section 2.2.1.4 for programming and erasing.

2.2.3.7 FLASH address register (FLASH_ADD)

Address offset: 0x14

Reset value: 0x0000 0000

31		 	-			-	 			 16
	1	I	I	 	FADD	[31:16]	 I	I	1	
	1		1		v	v		1	1	
15		 					 			 0
			1		FADD	[15:0]		1	1	
	•				v	v		•		

Bit field	Name	Description
31:0	FADD	Flash memory address
		Select the address to program when programming and the page to erase when erasing.
		Note: When the FLASH_STS.BUSY bit is '1', this register cannot be written.

2.2.3.8 FLASH option byte register (FLASH_OB)

Address offset: 0x1C

Reset value: 0x03FF FFDC

31	30				26	25							18	17	16

9:7	Reserved	Reserved, the reset value must be maintained							
6	NRST_PA0	PA0 pin configuration.							
		0: Common I/O pin							
		1: NRST pin							
		Note: This bit is read-only.							
5	BOOT_LOCK	Lock the first 3K of the main flash.							
		0: Not locked							
		1: Lock							
		Note : This bit is read-only. the first 3kb flash is not erasable when locked							
4	nRST_PD	The Power Down mode is used to reset the configuration							
		0: A reset occurs immediately after the system enters the Power Down mode. Even if the							
		system enters the Power Down mode, the system will be reset instead of entering the Power							
		Down mode.							
		1: The system does not reset after entering the Power Down mode.							
		Note: This bit is read-only.							
3	nRST_STOP	Enter the STOP mode to reset the configuration							
		0: A reset occurs immediately after entering the STOP mode. Even if the process of entering the							
		STOP mode is executed, the system will be reset instead of entering the STOP mode.							
		1: No reset is generated after the STOP mode is entered.							
		Note: This bit is read-only.							
2	WDG_SW	Watchdog Settings							
		0: Hardware watchdog.							
		1: Software watchdog.							
		Note: This bit is read-only.							
1	RDPRT1	Read protection level L1							
		0: L1 level of read protection is disabled.							

Bit field	Name	Description
		1: L1 read protection is enabled.
		Note: This bit is read-only.
0	OBERR	Option byte error
		When this bit is '1', the option byte does not match its inverse.
		Note: This bit is read-only.

		Filter width = $(1/f_{LSI}) \times (0)$	xFF - LVR	CNT).

2.2.3.10 VTOR register (FLASH_VTOR)

Address offset: 0x24

Bit field	Name	Description
31	VTOR_EN	VTOR enable
		0: Enables VTOR
		1: Disables VTOR
30:0	VTOR_VALUE	Used for interrupt vector remapping to store the first address of the interrupt vector table
		These bits are valid when $VTOR_EN = 1$.
		If the first address of the interrupt vector table needs to be remapped to the 0x08000C00, the
		VTOR_VALUE is configured to 0x08000C00.

3 Power control (PWR)

3.1 General description

The working voltage (V_{DD}) of N32G003 is 2V~5.5V. It mainly has two power domains: analog/digital power supplies. Please refer to Figure 3-1 Power block diagram. As the power control unit of the SOC, PWR's main function is to control N32G003 to enter/exit different power modes. The N32G003 supports RUN, STOP and PD modes.

3.1.1 **Power supply**

The functions of different power domains are described below, and the digital part of the power domain is described in the following sections of this document. Refer to Figure 3-1 for power block diagram.

- V_{DD}: The voltage input range is 2V~5.5V. It mainly provides power for PMU, HSI, etc.
- V_{DDD}: The voltage regulator provides power for CPU, AHB, APB, SRAM, FLASH and most digital peripherals.

The embedded voltage regulator is used to power the internal digital module. The voltage regulator has three modes: normal mode, low power mode and power down mode.

■ Normal mode (MR)

1.5V output (typical), mainly used in RUN mode.

■ Low-power mode (LPR)

Mainly used in STOP mode. In STOP mode, low-power consumption mode output voltage (1.5V/1.2V) can be configured for lower current consumption. The default output is 1.5V, and the V_{DDD} PDR trigger voltage is 1.2V. When PWR_CTRL5.STPMRSEL[1:0] = '01', output voltage 1.5V, PWR_CTRL.PDRS[1:0] must be configured for '11' (V_{DDD} PDR trigger voltage 1.2V); when PWR_CTRL5.STPMRSEL[1:0] = '11', output voltage 1.2V, PWR_CTRL.PDRS[1:0] must be configured as '10' (V_{DDD} PDR trigger voltage 1.0V).

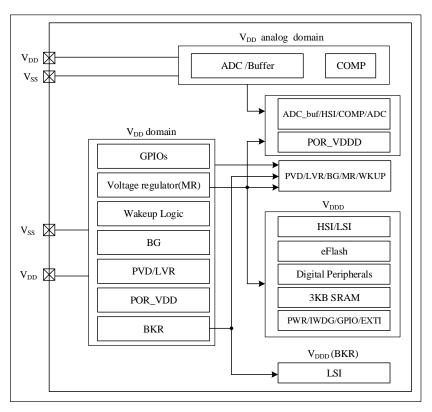

■ Power-down mode

Voltage regulator off, mainly used in PD mode.

Figure 3-1 Power supply diagram

3.1.2 **Power supply supervisor**

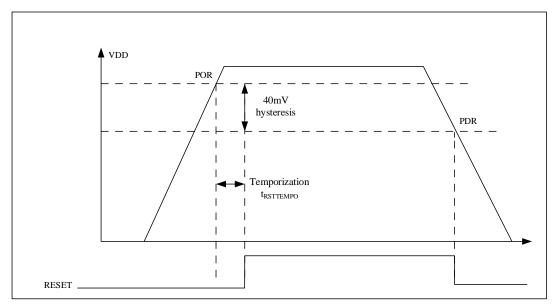

3.1.2.1 Power on reset (POR) / power down reset (PDR)

N32G003 has an integrated power-on reset (POR) and power-down reset (PDR) circuits, which can work at a minimum voltage of 2V and requires no external reset circuit. When V_{DD} is lower than the specified threshold ($V_{POR/PDR}$), N32G003 will remain in reset state.

For more information about the reset threshold of the switching power supply, please refer to the electrical characteristics section of the relevant data sheet.

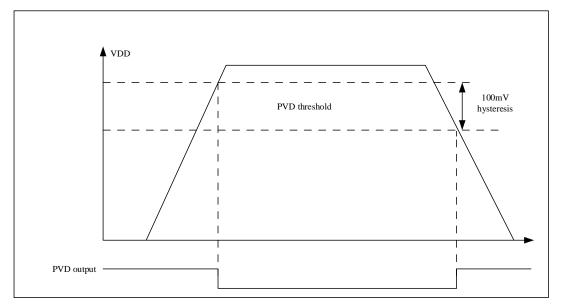

3.1.2.2 Programmable voltage detector (PVD)

PVD is used to detect V_{DD} voltage level. The threshold of PVD is controlled by PWR_CTRL.PLS [3:0]. PVD can be enabled/disabled by PWR_CTRL.PVDEN bit.

PWR_CTRLSTS.PVDO indicates whether V_{DD} is higher or lower than PVD threshold. This event also goes to EXTI line 18. If the EXTI register is enabled, an interrupt can be generated. When V_{DD} is lower than PVD threshold or when V_{DD} is higher than PVD threshold, PVD output interrupt can be generated according to the rising/falling edge configuration of EXTI line 18. For example, interrupt service routines can perform emergency shutdown.

3.1.2.3 Low voltage reset (LVR)

LVR is used to detect V_{DD} voltage level. The threshold of LVR is controlled by PWR_CTRL2.LVRLS [3:0]. LVR can be enabled/disabled by PWR_CTRL2.LVREN bit.

 $PWR_CTRL2.LVRO$ indicates whether V_{DD} is higher or lower than LVR threshold. This event also goes to system reset.

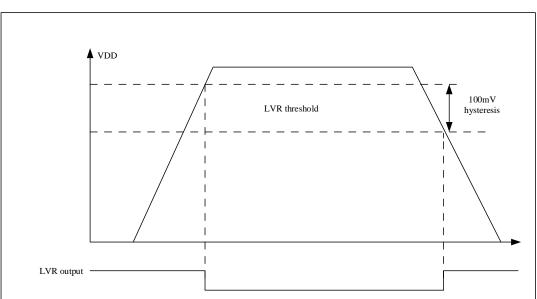

Figure 3-4 LVR threshold diagram

3.2 Power modes

N32G003 has 3 power modes: RUN, STOP, and PD. Different modes have different performance and power consumption. Please refer to the following Table for N32G003 power modes:

Mode	Condition	Enter	Exit
RUN	CPU running.	Power-on, system reset, low power	Entering STOP or PD
KUN	Peripheral running depending on configuration.	wake-up.	modes.
	CPU deep sleep mode.		
	The peripheral clock is turned off, and the voltage		
	regulator is still running in a low-power mode.		
	HSI is turned off.		
	LSI switch can be configured.	WFI/WFE:	
	All GPIO states are kept, and all SRAM and	1) SCB_SCR.SLEEPDEEP = 1, No	Any interrupt wake-up
STOP	registers keep data.	interrupt (for WFI) or event (for WFE) is	event by EXTI, NRST,
	All IO, PVD can be used to wake up the CPU. Or	pending.	IWDG.
	other peripherals (TIM6) can be configured to	2) PWR_CTRL.PDSTP = 0	
	wake up.		
	After waking up, the HSI is turned on, and the		
	code starts from where it was suspended.		
	Flash enters deep sleep mode.		
	The main voltage regulator is turned off, and the	WFI/WFE:	WKUP0/1 rising or
PD	HSI/LSI is turned off.	1) SCB_SCR.SLEEPDEEP = 1, No	falling edge can be

COMP	0	-	_	-	-				
SysTick timer	0	-	-	-	-				
CRC	0	-	-	-	-				
GPIOs	0	0	0	-	2 pins				

Table 3-2 Peripheral running status

Note:

1. *Y:* enable, *O:* optional (Disabled by default and enabled by software configuration), -: disable, DSTB: deep-standby.

2. The pins that can wake up from PD are PA1 (WKUP0), PA2 (WKUP1), NRST.

3.2.1 STOP mode

STOP mode is based on Cortex[®]-M0 deep sleep mode, combined with peripheral clock gating. Voltage regulator operates in low power mode. The output voltage (1.5V/1.2V) output is configurable. In STOP mode, disable as HSI. But the contents of SRAM and all registers are saved. Flash automatically enter deep sleep mode. In STOP mode, all I/O pins remain in the same state as in run mode.

3.2.1.1 Enter STOP mode

When entering STOP mode, need set $SCB_SCR.SLEEPDEEP = 1$ and $PWR_CTRL.PDSTP = 0$.

If a FLASH operation is in progress, the time to enter STOP mode will be delayed until the memory access is completed.

If the access to the APB area is in progress, the time to enter the STOP mode will be delayed until the APB access is completed.

In STOP mode, the following peripherals are available:

- Independent Watchdog (IWDG): The independent watchdog will be activated when its related register is written by software or by hardware operation. Once enabled, it will keep counting until a reset is generated.
- IO and TIM6/PVD peripherals can wake up.
- Internal RC oscillator (LSI RC): It can be turned on by the PWR_CTRL3.LSIEN.

ADC should be disabled when entering STOP mode to avoid unnecessary power consumption.

3.2.1.2 Exit STOP mode

When an interrupt or wake-up event wakes up STOP mode, the HSI RC oscillator is selected as the system clock, codes resumed from suspended location. Since the voltage regulator is in low power mode, it takes extra start-up time to wakes up from STOP mode. In addition, shorten the FLASH wake up time by set PWR_CTRL4.FLHWKUP = 1 before enter STOP.

3.2.2 **PD mode**

PD (Power Down) mode is based on Cortex®-M0 deep sleep mode, which can achieve lower power consumption. In this mode, the CPU, all peripherals, voltage regulator, HSI/LSI clock sources and all digital power supplies (V_{DDD}) are turned off, All GPIO pins are in a high-impedance state, where NRST/PA1_WKUP0/PA2_WKUP1 can be used to wake up PD mode.

3.2.2.1 Enter PD mode

When entering the PD mode, user needs to set SCB_SCR.SLEEPDEEP = 1 and PWR_CTRL.PDSTP = 1.

If a FLASH operation is in progress, entering PD mode will be delayed until memory access is complete.

If the access to the APB area is in progress, entering PD mode will be delayed until the APB access is complete.

3.2.2.2 Exit PD mode

When external reset (NRST pin) occurs, WKUP pin rising edge or falling edge events occur, MCU will exit PD mode. All registers are reset when wake up from PD mode.

After waking up from PD mode, code execution is equivalent to execution after reset (read reset vector, etc.).

3.3 Debug mode

By default, if application puts the MCU in STOP or PD mode while using the debugging feature, the debugging connection will be lost. Because the Cortex®-M0 core loses its clock.

However, by setting some configuration bits in the DBG_CTRL register, the software can be debugged even when the STOP and PD mode are used. If these register bits are configured, the voltage regulator and HSI will not be disabled or turned off.

3.3.1 Low power mode debug mode support

When debugging in low power mode, you need to ensure that the FCLK of the kernel is enabled to provide the necessary clock for kernel debugging. The software needs to configure the DBG_CTRL.STOP or DBG_CTRL.PD bit in the debug control register, start the internal RC oscillator and provide the clock for FCLK. For specific features and functions, see the description of DBG_CTRL.PD and DBG_CTRL.STOP bit fields in the DBG_CTRL register in Section 3.4.9.

3.3.2 **Peripheral debug support**

In addition to supporting debug in low power mode, it also supports some peripherals to stop working in debug state (TIM1, TIM3, TIM6, IWDG). When the corresponding bit of the peripheral control bit in the DBGCTRL register is set, the corresponding peripheral enters the debugging state after the kernel stops. For specific operations and features, please refer to the description of the other bit fields of the DBG_CTRL register in Section 3.4.9.

3.4 PWR registers

		1111 4.8v						
4	PVDEN	The Power voltage detector (PVD) enable.						
		0: PVD disabled.						
		1: PVD enabled.						
3	CLRDBGPDF	The software writes a '1' to this bit to clear the DBGPDF status bit. Always read as						
-		0.						
		0: Invalid. 1: Clear the DBGPDF status bit.						

Bit field	Name	Description
2	CLRWKUPF	Clear the wake-up bit.
		Always read as 0.
		0: Invalid.
		1: Clear WKUPF (write) after 2 system clock cycles.
1	PDSTP	Enter STOP/PD mode selection.
		0: CPU output DEEPSLEEP is '1', and the chip enters STOP mode.
		1: CPU output DEEPSLEEP is '1', and the chip enters PD mode.
0	IWDGRSTEN	IWDG reset enable control.
		0: IWDG reset request will not generate a system reset.
		1: IWDG reset request will generate a system reset.

3.4.3 **Power control status register (PWR_CTRLSTS)**

Address offset: 0x04

31															16
	1	1	1		1	1	Rese	rved	1	1	1		1		
15				11	10	9	8	7				3	2	1	0
	1	Reserved	1		WKUP POL	WKUP1 EN	WKUP0 EN			Reserved	1		PVDO	DBGPDF	WKUPF
					rw	rw	rw						r	r	r

Bit field	Name	Description
31:11	Reserved	Reserved, the reset value must be maintained.
10	WKUPPOL	Wakeup polarity for PA1/PA2. To wakeup PD mode by using rising edge or falling edge.
		Make sure disable wakeup enable before changing polarity value.
		0: Falling edge.
		1: Rising edge.
9	WKUP1EN	WKUP pin PA2 enable control.
		0: WKUP pin is used for general purpose I/O. An event on the WKUP pin does not wakeup
		the device from PD mode.
		1: WKUP pin is used for wakeup from PD mode.
		Note: This bit is reset by V_DDD POR Reset only.
8	WKUP0EN	WKUP pin PA1 enable control.
		0: WKUP pin is used for general purpose I/O. An event on the WKUP pin does not wakeup
		the device from PD mode.
		1: WKUP pin is used for wakeup from PD mode.
		Note: This bit is reset by VDDD POR Reset only.
7:3	Reserved	Reserved, the reset value must be maintained.
2	PVDO	PVD output.
		It is valid only if PWR_CTRL.PVDEN = 1.
		0: V _{DD} is higher than the PVD threshold selected with PWR_CTRL.PLS [3:0].

Bit field	Name	Description
		1: V_{DD} is lower than the PVD threshold selected with PWR_CTRL.PLS [3:0].
1	DBGPDF	DBGPD mode status bit.
		When entering DBGPD mode, hardware sets this bit to '1'.
		Hardware clears this bit when software sets PWR_CTRL.CLRDBGPDF = 1.
		Only V _{DDD} POR/PDR can reset this bit.
		0: Chip never entered DBGPD mode.
		1: Chip has entered DBGPD mode.
0	WKUPF	DBGPD mode wake-up status bit.
		This bit is set by hardware after WKUP pin wakes up DBGPD mode.
		Hardware clears this bit when software sets PWR_CTRL.CLRWKUPF = 1.
		Only V _{DDD} POR/PDR can reset this bit.
		0: No wakeup event occurred.
		1: A wakeup event was received from the WKUP pin.

3.4.4 **Power control register 2 (PWR_CTRL2)**

Address offset: 0x08

Reset value: 0x0000 0400

This register is write-protected. Each time the software writes to this register, it must first write the key 0xA5000000 (unlocked) to this register.

31							24	23		 				16

		1011 4.0v
		1100 4.2v
		1101 4.4v
		1110 4.6v
		1111 4.8v
10	LVREN	LVR enable.
		0: LVR disabled.
		1: LVR enabled.
9	LVRRSTEN	LVR reset Enable.
		0: LVR reset disabled.
		1: LVR reset enabled.
8	LVRFILEN	LVR filter Enable.
		0: LVR filter disabled.
		1: LVR filter enabled.
7:0	LVRCNT	LVR filter control count value.
		0x00: Not filtered
		0xFF: Maximum filtering width
		Filter width = $(1/f_{LSI}) \times LVRCNT$.

3.4.5 **Power control register 3 (PWR_CTRL3)**

Address offset: 0x14

Reset value: 0x0000 0EAF

Bit field	Name	Description			
31:13	Reserved	Reserved, the reset value must be maintained.			
12:10	LSISTPCNT	After exit STOP, user can delay starting the LSI to stabilize the LSI. The delay is			
		determined by the LSISTPCNT configuration.			

Nations Technologies Inc. Tel: +86-755-86309900 Email: info@nationstech.com Address: Nations Tower, #109 Baoshen Road, Hi-tech Park North. Nanshan District, Shenzhen, 518057, P.R.China

Bit field	Name	Description
		Note: These bits are used with PWR_CTRL3.LSIEN.
9	PDRSEL	0: V _{DDD} PDR selection signal is pulled high by default. In this case, PWR_CTRL.PDRS
		[1:0] == '11'.
		1: V _{DDD} PDR selection is controlled by PWR.
8	Reserved	Reserved, the reset value must be maintained.
7	LSIEN	Control PWR to enable LSI.
		0: PWR (always included in STOP mode) request to enable LSI.
		1: After entering STOP, PWR no longer requests to enable LSI.
6	HSISEL	HSI frequency trim select.
		0: HSI 48M trim.
		1: HSI 40M trim.
5	HSIPWR	HSI controller select
		0: HSI is not controlled by PWR.
		1: HSI is controlled by PWR.
		Note: After this bit is enabled, you can configure PWR_CTRL3.HSISEL
4:0	Reserved	Reserved, the reset value must be maintained.

3.4.6 **Power control register 4 (PWR_CTRL4)**

Address offset: 0x20

Reset value: 0x0000 0000

This register is write-protected. Each time the software writes to this register, it must first write the key $0x0175_3603$ (unlocked) to this register.

31			1				1				1				16
	1	I	I	I		1	Rese	erved	I	1		I	I		'

		•													·

Bit field	Name	Description
31:3	Reserved	Reserved, the reset value must be maintained.
2	RUNF	RUN mode flag.
		0: System not in RUN mode.
		1: System in RUN mode.
1	STBFLH	Flash deep standby mode enable (configurable in RUN mode)
		This bit is set and reset by software, or reset by hardware in STOP and PD modes.
		0: After the software clears this bit, Flash exit the deep standby mode and return to the
		normal operating mode.
		1: After the software set this bit to '1', the Flash enter deep standby mode.
0	FLHWKUP	Enable Flash fast wake-up.

Bit field	Name	Description
		0: When the chip exits from STOP mode, use Flash to wake up normally.
		1: When the chip exits from STOP mode, use Flash to wake up quickly.
		Note: Please refer to the data sheet for the wake-up time.

3.4.7 **Power control register 5 (PWR_CTRL5)**

Address offset: 0x24

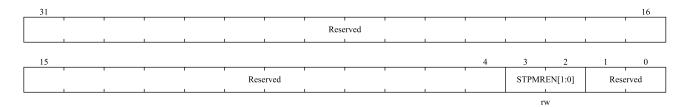

Reset value: 0x0000 0004

31	-	-		 	-			 			-		16
			1			Rese	erved	1	1				
15		•			•				4	3	2	1	0

										r	w		

Bit field	Name	Description
31:4	Reserved	Reserved, the reset value must be maintained.
3:2	STPMRSEL[1:0]	After the chip enters STOP mode, V _{DDD} output voltage is selected. Before configuring
		this register bit, the software must first configure PWR_CTRL6.STPMREN = '11'.
		00: No used.
		01: V _{DDD} output voltage 1.5V.
		10: Reserved.
		11: V _{DDD} output voltage 1.2V.
		This bit is reset by V _{DDD} POR only.
1:0	Reserved	Reserved, the reset value must be maintained.

3.4.8 **Power control register 6 (PWR_CTRL6)**

Address offset: 0x28

Bit field	Name	Description
31:4	Reserved	Reserved, the reset value must be maintained.

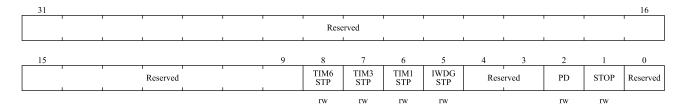

Bit field	Name	Description
3:2	STPMREN[1:0]	V _{DDD} Output voltage selection enable.
		00: Enter STOP mode, V _{DDD} Output voltage 1.5V.
		01/10: Reserved.
		11: Enter STOP mode, V_{DDD} Output voltage control by PWR_CTRL5.STPMRSEL.
		This bit is reset by V_{DDD} POR only.
1:0	Reserved	Reserved, the reset value must be maintained.

3.4.9 **Debug control register (DBG_CTRL)**

Address offset: 0x30

Reset value: 0x0000 0000

Only V_{DDD} POR/PDR can reset this register. Only after the Debugger is connected, the software can write access to this register.

Bit field	Name	Description
31:9	Reserved	Reserved, the reset value must be maintained.
8	TIM6STP	The counter of TIM6 stops working when the kernel enters the debug state.
		Set or cleared by software.
		0: The counter of TIM6 still works normally.
		1: The counter of TIM6 stops working.
7	TIM3STP	The counter of TIM3 stops working when the kernel enters the debug state.
		Set or cleared by software.
		0: The counter of TIM3 still works normally.
		1: The counter of TIM3 stops working.
6	TIM1STP	The counter of TIM1 stops working when the kernel enters the debug state.
		Set or cleared by software.
		0: The counter of TIM1 still works normally.
		1: The counter of TIM1 stops working.
5	IWDGSTP	The counter of IWDG stops working when the kernel enters the debug state.
		Set or cleared by software.
		0: The counter of IWDG still works normally.
		1: The counter of IWDG stops working.
4:3	Reserved	Reserved, the reset value must be maintained.

Bit field	Name	Description
2	PD	Debug PD mode control.
		Set or cleared by software.
		0: (FCLK off, HCLK off) system enters PD mode, digital circuit part is unpowered.
		From a software point of view, exiting PD mode is the same as a power-on reset.
		1: (FCLK on, HCLK on) system enters DBGPD mode, digital circuit part is powered,
		and FCLK clock is provided by the internal RC oscillator. In addition, the
		microcontroller exits DBGPD mode by generating a system reset, which is the same as a
		system reset.
1	STOP	Debug STOP mode control.
		Set or cleared by software.
		0: (FCLK off, HCLK off) system enters STOP mode, clock controller disables all clocks
		(including HCLK and FCLK). When exiting STOP mode, the configuration of the clock
		is the same as after reset (Microcontroller is clocked by the 48MHz internal RC
		oscillator (HSI)).
		1: (FCLK on, HCLK on) system enters DBGSTOP mode, FCLK clock is provided by
		the internal RC oscillator.
0	Reserved	Reserved, the reset value must be maintained.

4 Reset and clock control (RCC)

4.1 Reset Control Unit

N32G003 supports the following two types of reset:

- Power Reset
- System Reset

4.1.1 **Power reset**

A Power reset occurs in the following circumstances:

- Power-on/ Power-down reset (POR/PDR reset).
- When exiting PD mode.

A power reset sets all registers to their reset values.

4.1.2 System reset

A system reset is generated when one of the following events occurs:

- A low level on the NRST pin (external reset)
- Independent watchdog end of count condition (IWDG reset)
- Software reset (SW reset)
- Low power management reset
- EMC reset
- LVR reset

Except for the following registers, a system reset will reset all registers to their reset states:

- RCC_CTRLSTS
- RCC_EMCCTRL
- PWR_CTRL.PDRS[1:0], PWR_CTRL.NRSTPOL
- PWR_CTRLSTS.WKUPF, PWR_CTRLSTS.WKUP0EN, PWR_CTRLSTS.WKUP1EN, PWR_CTRLSTS. WKUPPOL
- PWR_CTRL3.HSISEL
- DBG_CTRL

The reset source can be identified by checking the reset flags in the Control/Status Register (RCC_CTRLSTS).

4.1.2.1 Software reset

A software reset can be generated by setting the SYSRESETREQ bit in Cortex®-M0 Application Interrupt and Reset

Control Register. Refer to Cortex[®]-M0 technical reference manual for further information.

4.1.2.2 Low-power management reset

Low-power management reset can be generated by using the following methods:

- Low-power management reset generated when entering PD mode: This reset is enabled by resetting the nRST_PD bit in User Option Bytes. In this case, whenever a PD mode entry sequence is successfully executed, the system is reset instead of entering PD mode.
- Low-power management reset generated when entering STOP modes: This reset is enabled by resetting the nRST_STOP bit in User Option Bytes. In this case, whenever a STOP mode entry sequence is successfully executed, the system is reset instead of entering STOP modes.

The reset source will act on the NRST pin and remain low during reset. The reset entry vector is fixed at address 0x0000_0004. For more details, see Table 6-1 Vector table.

The system reset signal provided to the chip is output on the NRST pin. The pulse generator guarantees a minimum reset pulse duration of 20µs for each reset source (external or internal). For external reset, the reset pulse is generated while the NRST pin is asserted low.

The Figure below shows the system reset generation circuit.

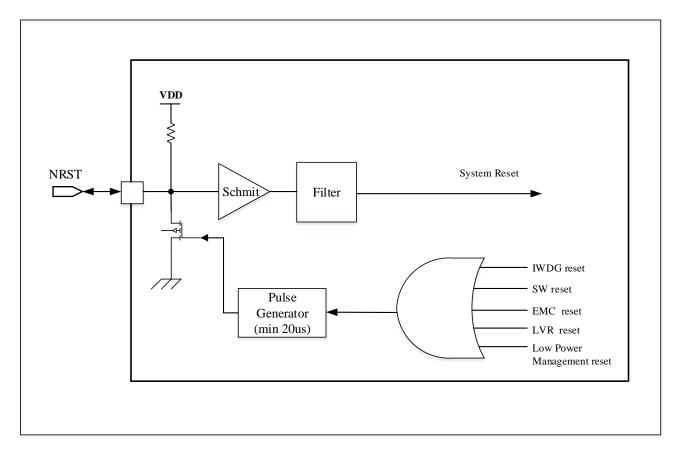

Figure 4-1 System reset generation

4.2 Clock control unit

The HSI oscillator clock source is used to drive the system clock (SYSCLK).

The 32KHz low-speed internal RC is used as a secondary clock source, which can be programmed to drive an independent watchdog (IWDG), TIM6 (for wake-up STOP mode).

The frequency of the AHB, APBdomains can be configured by the user through multiple prescalers. The maximum allowable frequency of the AHB domain, APB domain is 48MHz.

All peripheral clocks are derived from the system clock (SYSCLK) except in the following cases:

- ADC working clock source and ADC1M clock source are HSI
- By configuring RCC_CFG2.TIM1CLKSEL, you can select one of the following two cases as the TIM1 working clock source:
 - ♦ APB clock (PCLK)
 - ♦ LSI clock
- By configuring RCC_CFG2.TIM6CLKSEL, you can select one of the following two cases as the TIM1 working clock source:
 - ♦ APB clock (PCLK)
 - ♦ SYSCLK

When the timer clock source is PCLK, timer clock frequency is automatically set by hardware in the following 2 cases:

- \diamond If the corresponding APB prescaler is 1, the timer clock frequency is the same as the APB frequency.
- \diamond If the corresponding APB prescaler is not 1, the timer clock frequency is twice the APB frequency.
- IWDG clock source is LSI oscillator.
- Flash memory programming interface clock is always the HSI clock
- By configuring the SysTick control and status registers, you can select one of the following two cases as the SysTick clock source:
 - AHB clock (HCLK) divided by 8
 - ♦ AHB clock (HCLK)

FCLK is the free running clock of the Cortex®-M0. See ARM's Cortex®-M0 Technical Reference Manual for details.

4.2.1 Clock Tree Diagram

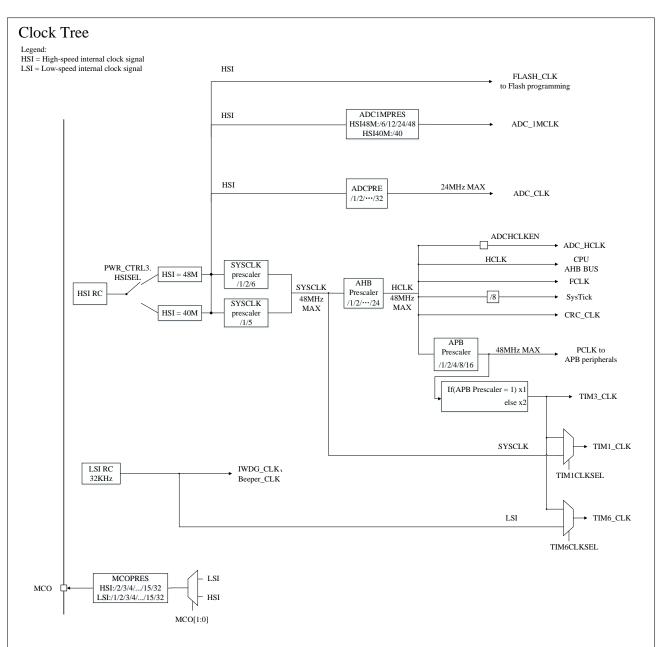

Figure 4-2 Clock Tree

1. The maximum frequency available for the system clock is 48MHz.

2. For more details about the internal and external clock source characteristics, please refer to the "Electrical Characteristics" section in the product datasheet.

4.2.2 HSI clock

By configuring PWR_CTRL5.HSISEL, Select HSI (High Speed Internal) clock signal is generated by an internal 48MHz or 40MHz RC oscillator, which can be used directly as a system clock or input after dividing. The HSI RC

oscillator provides a clock source without any external devices.

RC oscillator frequencies can vary from one chip to another due to manufacturing process variations. Therefore, the HSI clock frequency of the chip has been calibrated to 1% (25 °C) before leaving the factory.

If the user application is subject to voltage or temperature variations, this may affect the accuracy of the RC oscillator. The HSI frequency can be trimmed by using the RCC_HSICTRL.HSITRIM[3:0] bits.

The RCC_CTRL.HSI48MRDF or RCC_CTRL.HSI40MRDF bit flag indicates if the HSI RC oscillator is stable. At startup, the HSI RC output clock is not released until this bit is set by hardware.

4.2.3 LSI clock

The LSI RC can provide clock the IWDG and PWR in STOP mode. The LSI clock frequency is about 32KHz. Please refer to the electrical characteristics section of the data sheet for further information.

The RCC_LSICTRL.LSIRDF bit flag indicates if the LSI clock is stable. At startup, the clock is not released until this bit is set by hardware.

4.2.3.1 LSI calibration

Internal low-speed oscillator LSI frequency errors can be calibrated to obtain higher accuracy LPTIM (when clocked by LSI), Beeper, and IWDG time bases.

The LSI calibration steps are as follows:

- 1. Enable RCC_LSICTRL.LSIDETEN, which initiates LSI clock calibration;
- 2. Check RCC_LSICTRL.LSIDETFF flag bit, 1 indicates the end of calibration, read RCC_LSICTRL.LSIFREQ[15:0];
- 3. Take the average of the RCC_LSICTRL as many times as needed, and then cleared RCC_LSICTRL.LSIDETFF flag, disable RCC_LSICTRL.LSIDETEN;
- 4. Calculate actual LSI frequency according to the formula, LSICLK(kHz) = 8*HSICLK/LSIFREQ[15:0] (HSICLK is 48000kHz or 40000kHz);
- 5. Adjust the RCC_LSICTRL.LSITRIM[4:0] (default 16, adjustable step size 1kHz) according to the deviation of the actual LSI frequency from 32kHz

4.2.4 System clock (SYSCLK) selection

After the system reset, the HSI oscillator is selected as the system clock.

By configuring the HSI divider factor RCC_CFG.SYSPRES[1:0], when the HSI is 48M, the system clock can be configured to 8M, 24M, or 48M; When the HSI is 40M, the system clock can be configured to 8M or 40M.

4.2.5 Watchdog clock

If the independent watchdog has been started by hardware option or software, the LSI oscillator will be forced on and cannot be turned off. The clock is supplied to the IWDG after the LSI oscillator is stable.

4.2.6 **TIM6 clock**

In normal working mode, the TIM6 clock supports 2 clock sources: PCLK and LSI. Since PCLK will be turned off in low power mode, software should switch the TIM6 clock to LSI before entering low power mode.

When LSI and PCLK are switched between each other, software must ensure that both clocks are turned on to switch without glitches.

4.2.7 Clock output(MCO)

The microcontroller clock output (MCO) capability allows the clock signal to be output onto the external MCO pin.

MCO pin is PA13, the corresponding GPIO port register must be configured for the corresponding function.

The following 2 clock signals can be selected as the MCO clock:

- HSI clock division
- LSI clock division

The MCO clock is selected by RCC_CFG.MCO[1:0], and the clock is divided by RCC_CFG.MCOPRES[3:0].

4.3.2 HSI clock control register (RCC_HSICTRL)

Address offset: 0x00

Bit field	Name	Description
31:8	Reserved	Reserved, the reset value must be maintained.
7:4	HSITRIM[3:0]	Internal high-speed clock trimming
		Written by software to calibrate the frequency of the internal HSI RC oscillator for
		higher accuracy as required by the application.
		The default value is 8, and the HSITRIM adjustment step is target frequency * 0.33%
		(the target frequency is 48M or 40M).
3:2	Reserved	Reserved, the reset value must be maintained.
1	HSI48MRDF	Internal 48M high-speed clock ready flag
		Set by hardware to indicate that internal 48 MHz RC oscillator is stable.
		0: internal 48 MHz RC oscillator not ready
		1: internal 48 MHz RC oscillator ready
0	HSI40MRDF	Internal 40M high-speed clock 40M ready flag
		Set by hardware to indicate that internal 40 MHz RC oscillator is stable.

Bit field	Name	Description
		0: internal 40 MHz RC oscillator not ready
		1: internal 40 MHz RC oscillator ready

4.3.3 Clock configuration register (RCC_CFG)

Address offset: 0x04

		1111: LSI/HSI clock is divided by 32 as MCO clock
27	Reserved	Reserved, the reset value must be maintained.
26:25	MCO[1:0]	Microcontroller clock output selection
		Set and cleared by software.
		00: no clock
		01: LSI clock
		10: LSE clock
		Others: Not allowed to set

Bit field	Name	Description
		Note: This clock output may be truncated at startup or during MCO clock source
		switching.
		When the HSI clock is selected to output to the MCO pin, the output clock frequency
		must not exceed the maximum I/O speed (For details of the maximum frequency of the
		I/O port, see the data sheet).
24:14	Reserved	Reserved, the reset value must be maintained.
13:12	SYSPRES[1:0]	Sysclk prescaler
		Set and cleared by software to control the division factor of the sysclk clock.
		When HSI is 48M:
		00: HSI not divided as sysclk
		01: HSI divided by 2 as sysclk
		Others: HSI divided by 6 as sysclk
		When HSI is 40M:
		00: HSI not divided as sysclk
		Others: HSI divided by 5 as sysclk
		Note: After exiting STOP, the bit reverts to the reset value.
11	Reserved	Reserved, the reset value must be maintained.
10:8	APBPRES[2:0]	APB prescaler
		Set and cleared by software to control the division factor of the APB clock(PCLK).
		0xx: HCLK not divided
		100: HCLK divided by 2
		101: HCLK divided by 4
		110: HCLK divided by 8
		111: HCLK divided by 16
7:4	AHBPRES[3:0]	AHBPRE: AHB prescaler
		Set and cleared by software to control the division factor of the AHB clock(HCLK).
		0xxx: SYSCLK not divided
		1000: SYSCLK divided by 2
		1001: SYSCLK divided by 4
		1010: SYSCLK divided by 8
		1011: SYSCLK divided by 12
		1100: SYSCLK divided by 16
		Others: SYSCLK divided by 24
3:0	Reserved	Reserved, the reset value must be maintained.

0	EMCDETEN	EMC clamp detect enable	
		Set and cleared by software.	
		0: Disable detect	
		1: Enable detect	

5 GPIO and AFIO

5.1 Summary

Supports 18 GPIO, divided into 2 groups (GPIOA/GPIOB), GPIOA have 16 pins, GPIOB has 2 pins. Each GPIO pin can be configured by software as output (push-pull or open drain), input (with or without pull-up or pull-down) or alternate peripheral function ports (output/input), most GPIO pins are shared with digital or analog reuse peripherals, some IO pins are also reused with clock pins. Except for ports with analog input function, all GPIO pins have the ability to pass through a large current.

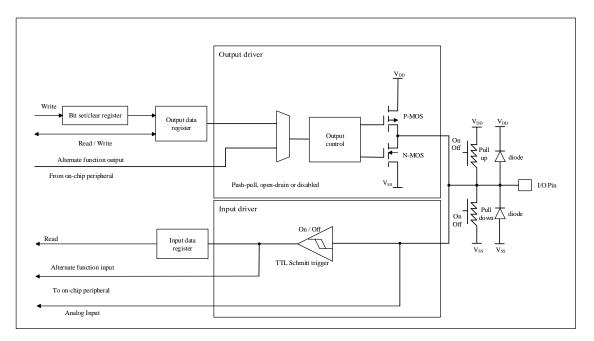

GPIO ports have the following features:

- GPIO port can be configured with the following modes by software:
 - ♦ Input floating
 - ♦ Input pull-up
 - Input pull-down
 - Analog function
 - Open drain output and pull-up/pull-down can be configured
 - Push-pull output and pull-up/pull-down can be configured
 - Push-pull alternate function and pull-up/pull-down can be configured
 - Open-drain alternate function and pull-up/pull-down can be configured
- Individual bit setting or bit clearing function
- All I/O support external interrupt function
- All I/O support low power mode wake up, rising or falling edge configurable
 - 18 EXTI can be used for wake up in STOP mode, and all I/O can be reused as EXTI
 - NRST(PA0)/PA1/PA2 three wake up IOs can be used for PD mode wake up, I/O filtering time maximum lus
- Supports software remapping I/O alternate function
- Support GPIO lock mechanism, reset the lock state to clear

Each I/O port bit can be programmed arbitrarily, but the I/O port register must be accessed as a 32-bit word (16-bit half-word or 8-bit byte are not allowed). The following figure shows the basic structure of an I/O port.

Figure 5-1 Basic structure of an I/O port

5.2 IO function description

5.2.1 **IO mode configuration**

The I/O port mode can be configured through the registers GPIOx_PMODE (x=A to B), GPIOx_POTYPE (x=A to B) and GPIOx_PUPD (x=A to B). The configuration of different operation modes is shown in the following table:

PMODE[1:0]	POTYPE	PUP	D[1:0]	The I/O configuration
	0	0	0	General-purpose output push-pull
	0	0	1	General-purpose output push-pull + pull-up
	0	1	0	General-purpose output push-pull + pull-down
01	0	1	1	Reserved
01	1	0	0	General-purpose output open-drain
	1	0	1	General-purpose output open-drain + pull-up
	1	1	0	General-purpose output open-drain + pull-down
	1	1	1	Reserved
	0	0	0	Alternate function push-pull
	0	0	1	Alternate function push-pull + pull-up
	0	1	0	Alternate function push-pull + pull-down
10	0	1	1	Reserved
	1	0	0	Alternate function open-drain
	1	0	1	Alternate function open-drain + pull-up
	1	1	0	Alternate function open-drain + pull-down

Table 5-1 Relationship between I/O modes and configurations

Nations Technologies Inc. Tel: +86-755-86309900 Email: info@nationstech.com Address: Nations Tower, #109 Baoshen Road, Hi-tech Park North. Nanshan District, Shenzhen, 518057, P.R.China

PMODE[1:0]	POTYPE	PUPD[1:0]		The I/O configuration
	1	1	1	Reserved
	Х	0	0	Input floating
00	Х	0	1	Input pull-up
00	Х	1	0	Input pull-down
	х	1	1	Reserved
	Х	0	0	Analog
11	Х	0	1	
	Х	1	0	Reserved
	Х	1	1	

In addition, the GPIOx_DS.DSy (x=A to B) bit can be used to configure the high/low drive strength, and the GPIOx_SR.SRy (x=A to B) bit can be used to configure the fast/slow slew rate.

The input and output characteristics of I/O under different configurations are shown in the following table:

Characteristic	GPIO input	GPIO output	Analog input	Peripheral alternate
Output buffer	Disable	Enable	Disable	Configure according to peripheral function
Schmitt trigger	Enable	Enable	Disable The output value is	Enable
Pull-up/pull-down/floating	Configured	Configured	forced to be 0 Disable	Configure according to peripheral function
Open-drain mode	Disable	Can be configured, GPIO output 0 when output data is "0", high resistance of GPIO when "1"	Disable	Can be configured, GPIO output 0 when output data is "0", high resistance of GPIO when "1"
Push-pull mode	Disable	Can be configured, GPIO output 0 when output data is "0", GPIO output 1 when output data is "1"	Disable	Can be configured, GPIO output 0 when output data is "0", GPIO output 1 when output data is "1"
Input data register (IO state)	Readable (I/O status)	Readable (I/O status)	Read as 0 (Schmitt OFF)	Readable (I/O status)
Output data register (Output value)	Invalid (last written value)	Readable and written	Invalid (last written value)	Readable

5.2.1.1 **Input mode**

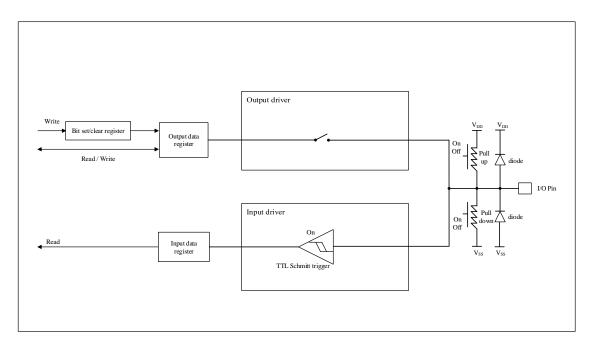

When I/O port is configured in input mode:

- Output buffer is disabled
- The schmidt trigger input is activated

- Whether the pull-up and pull-down resistors are connected depends on the configuration of the GPIOx_PUPD (x=A to B) register
- The data that appears on the I/O pin is sampled to the input data register on each APB clock
- Read access to the input data register can get I/O status

Figure 5-2 Input mode

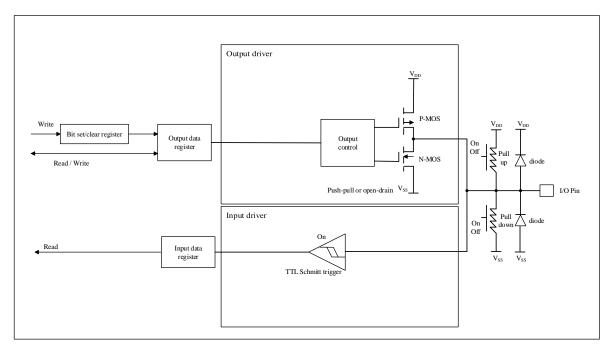

5.2.1.2 **Output mode**

When I/O port is configured as output mode:

- The schmidt trigger input is activated
- Whether the pull-up and pull-down resistors are connected depends on the configuration of the GPIOx_PUPD (x=A to B) register
- The output buffer is activated.
 - Open drain mode: '0' on the output register activates the N-MOS, the pin outputs a low level. while '1' on the output register puts the port in a high resistance state (P-MOS is never activated).
 - Push-pull mode: '0' on the output register activates the N-MOS, the pin outputs a low level. While '1' on the output register activates the P-MOS, the pin outputs a high level.
- The data that appears on the I/O pin is sampled to the input data register on each APB clock.
- Read access to input data register to get I/O status.
- Read access to the output data register to get the last written value.

Figure 5-3 Output mode

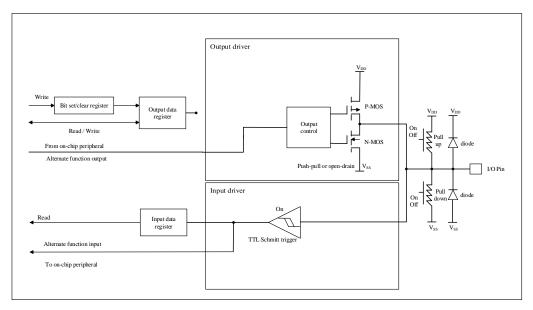

5.2.1.3 Alternate functional mode

When the I/O port is configured as alternate function mode:

- The schmidt trigger input is activated.
- Whether the pull-up and pull-down resistors are connected depends on the configuration of the GPIOx_PUPD (x=A to B) register
- In the open-drain or push-pull configuration, the output buffer is controlled by the peripheral.
- Signal-driven output buffers for built-in peripherals.
- At each APB clock cycle, the data appearing on the I/O pin is sampled into the input data register.
- Read access to input data register to get I/O status.
- Read access to the output data register to get the last written value.

Figure 5-4 Alternate function mode

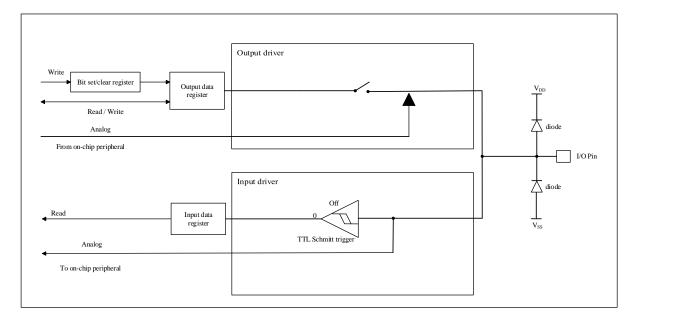

5.2.1.4 Analog mode

When the I/O port is configured as analog mode :

- The pull-up and pull-down resistors are disabled.
- Read access to the input data register gets the value "0".
- The output buffer is disabled.
- Schmitt trigger input is disabled and output value is forced to '0' (achieves zero consumption on each analog I/O pin).

5.2.2 Status after reset

During and just after reset, the alternate functions are not active, and the I/O ports are configured as analog mode (GPIOx_PMODE.PMODEy[1:0] = 11). However, with the exception of the I/O ports below.

 $\blacksquare NRST (PA0) :$

- ♦ NRST input pull-up
- ◆ FLASH_OB.NRST_PA0=1 (default): as NRST pull-up input
- FLASH_OB.NRST_PA0=0: as a normal GPIO, it cannot be connected low level during power-on when used as an input (otherwise the chip will always be in reset)
- After reset, debug system-related pins are configured to SWD interface I/O configuration by default:
 - PA9: SWCLK in input pull-down mode
 - PA8: SWDIO in input pull-up mode

5.2.3 Individual bit setting and bit clearing

By writing '1' to the bit to be changed in the bit set/clear register (GPIOx_PBSC) (x=A to B) and bit clear register (GPIOx_PBC) (x=A to B), the individual bit operation of the data register (GPIOx_POD) (x=A to B) can be realized, and one or more bits can be set/clear. The bit written with '1' is set or cleared accordingly, and the bit not written with '1' will not be changed. The software does not need to disable interrupts, and is completed in a single APB write operation.

5.2.4 External interrupt/wake-up line

All ports have external interrupt capability, which can be configured in the EXTI module:

- In order to use an external interrupt line, the port must be configured in input mode
- All ports can be configured for STOP mode wake-up, supporting rising or falling edge configurable.
- NRST(PA0)/PA1_WKUP0/PA2_WKUP1 can be used for PD mode wake up, with independent wake-up enable, support rising edge / falling edge can be configured, need to configure before entering PD mode.
- General purpose I/O ports are connected to 18 external interrupt/event lines, configured by registers AFIO_CFG.EXTI_SEL[4:0].

5.2.5 Alternate function

When I/O ports are configured for alternate function mode, the port bit configuration register (GPIOx_AFL,GPIOx_AFH,GPIOx_PMODE, GPIOx_POTYPE and GPIOx_PUPD) must be programmed before using. The alternate input or output is determined by the peripheral.

5.2.5.1 Software remaping I/O alternate function

To expand the flexibility of alternate peripheral functions under different device packages, some peripheral alternate functions can be remapped to other pins. Each I/O has up to 16 alternate functions (AF0~AF15). After reset, except for PA8 and PA9, other pins' alternate function is AF15(AFSELy = AF15). The I/O alternate function can be remapped by software configuring the corresponding registers (GPIOx_AFL/ GPIOx_AFH).

At this time, the alternate functions are no longer mapped to their original pins (For the I/O alternate function of the peripheral, if it is remapped to a different pin, then the input is remapping choose one of multiple, and the output will be connected to the remapped position, and the original position will be disconnected).

EXTI line input	External interrupt input	Input floating or input + pull-up or input + pull-down

5.2.7 GPIO locking mechanism

The locking mechanism allows to freeze contents of I/O configuration (GPIOx_PMODE, GPIOx_POTYPE, GPIOx_PUPD, GPIOx_DS, and GPIOx_SR) and alternate function registers (GPIOx_AFL and GPIOx_AFH). When the lock program is executed on one port bit, the configuration of that port bit will no longer be changed until the next reset, referring to the port configuration lock register GPIOx_PLOCK.

PLOCKK, that is, GPIOx_PLOCK [16], becomes 1 only after the correct sequence w1-> w0-> w1-> r0 (r0 here is also a must). After that, it becomes 0 only if the system reset is performed. GPIOx_PLOCK.PLOCK[15:0]

can only be modified at GPIOx_PLOCK.PLOCKK=0.

- The lock sequence to set GPIOx_PLOCK.PLOCKK bit, w1-> w0-> w1-> r0 will be valid only if the value (1 or 0) in GPIOx_PLOCK.PLOCK [15:0] does not change during this sequence. The GPIOx_PLOCK.PLOCKK bit will not be set if the value in GPIOx_PLOCK.PLOCK [15:0] changes during this sequence.
- As long as GPIOx_PLOCK.PLOCKK=0 and GPIOx_PLOCK.PLOCKy = 0 or 1, all configuration and alternate function bits can be modified. When GPIOx_PLOCK.PLOCKK=1 but GPIOx_PLOCK.PLOCKy = 0, the corresponding configuration and alternate function bits corresponding to GPIOx_PLOCK.PLOCKy = 0 can be modified.
- Only when GPIOx_PLOCK.PLOCKK=1 and GPIOx_PLOCK.PLOCKy = 1, the configurations corresponding to GPIOx_PLOCK.PLOCKy = 1 are locked and can not be modified.
- If the lock sequence operation is wrong, then it must be redone (w1-> w0-> w1-> r0) to initiate the lock operation again.

5.3 GPIO registers

These peripheral registers must be operated in 32-bit word mode.

GPIOA base address: 0x4000 1C00.

GPIOB base address: 0x4000 2000.

w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bit Field	Name	Description
31:16	РВСу	Clear bit y of port GPIOx $(x = A,B)$
		These bits can only be written.
		0: The corresponding GPIOx_POD.PODy bit is not affected
		1: Clears the corresponding GPIOx_POD.PODy bit to 0
		Note: If the corresponding bits of PBSy and PBCy are set at the same time, the
		PBSy bits take effect.
		<i>Note:</i> $x = A$, $y = 015$.
		x = B, y = 0, I.
15:0	PBSy	Set bit y of port GPIOx ($x = A,B$)
		These bits can only be written.
		0: The corresponding GPIOx_POD.PODy bit is not affected
		1: Sets the corresponding GPIOx_POD.PODy bit to 1
		<i>Note:</i> $x = A, B, y = 015$.
		x = B, y = 0, 1.

5.3.10 GPIO port bit clear register (GPIOx_PBC)

Address offset: 0x28

Reset value (Port A) : 0x0000 0000

31															16
	•		I	I			Rese	rved	I	I	1		I		'
	I		I	I		I			I		I	L			
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PBC15	PBC14	PBC13	PBC12	PBC11	PBC10	PBC9	PBC8	PBC7	PBC6	PBC5	PBC4	PBC3	PBC2	PBC1	PBC0
w	w	w	w	w	w	w	w	W	w	w	w	w	w	W	w

Bit Field	Name	Description
31:16	Reserved	The reset value must be maintained.

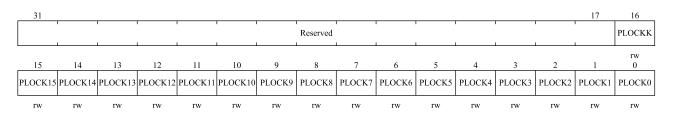

Bit Field	Name	Description
15:0	РВСу	Clear bit y of port GPIOx $(x = A,B)$
		These bits can only be written.
		0: The corresponding GPIOx_POD.PODy bit is not affected
		1: Clears the corresponding GPIOx_POD.PODy bit to 0
		<i>Note:</i> $x = A$, $y = 015$.
		x = B, y = 0, 1.

5.3.11 GPIO port lock register (GPIOx_PLOCK)

Address offset: 0x1C

Reset value (Port A) : 0x0000 0000

Bit Field	Name	Description
31:17	Reserved	The reset value must be maintained.
16	PLOCKK	Lock key
		This bit can be read anytime. It can only be modified using the lock key writing
		sequence.
		0: Port configuration lock key not active
		1: Port configuration lock key active. GPIOx_PLOCK register is locked until an MCU
		reset occurs.
		Lock key writing sequence:
		Write 1 -> write 0 -> write 1 -> read 0 -> read 1
		The last reading can be omitted, but it can be used to confirm that the lock key has
		been activated.
		Note: During the lock key writing sequence, the value of PLOCK[15:0] must not
		change. Any error in the lock sequence will abort the lock.
15:0	PLOCKy	Configuration lock bit y of port GPIOx $(x = A,B)$
		These bits are readable and writable but can only be written when the PLOCKK bit is
		0.
		0: Do not lock the configuration of the port
		1: Lock the configuration of the port
		<i>Note:</i> $x = A$, $y = 015$.
		x = B, y = 0, 1.

5.3.12 GPIO alternate function low register (GPIOx_AFL)

		01100: Select PA12 to trigger the conversion
		01101: Select PA13 to trigger the conversion
		01110: Select PA14 to trigger the conversion
		01111: Select PA15 to trigger the conversion
		10000: Select PB0 to trigger the conversion
		10001: Select PB1 to trigger the conversion

6 Interrupts and events

6.1 Nested vectored interrupt controller

Features

- 16 maskable interrupt channels (not including 16 Cortex[®]-M0 interrupt line);
- 4 programmable priorities (using 2 bit interrupt priorities);
- Low latency exception and interrupt handling;
- Power management control;
- The realization of system control register;

The Nested Vector Interrupt Controller (NVIC) is closely linked to the processor core, enabling low latency interrupt processing and efficient processing of late interrupts. The nested vector interrupt controller manages interrupts including core exceptions.

6.1.1 SysTick calibration value register

The system tick calibration value is fixed at 6000. When the system tick clock is set to 6MHz (when clock source is HCLK/8), 1 ms time reference is generated.

6.1.2 Interrupt and exception vectors.

Position	Priority	Priority type	Name	Description	Address
-	-	-	-	Reserved	0x0000 0000
-	-3	Fixed	Reset	Reset	0x0000 0004
-	-2	Fixed	NMI	Non-maskable interrupt.RCC clock security system (CSS) is connected to the NMI vector.	0x0000 0008
-	-1	Fixed	HardFault	All types of errors (fault)	0x0000 000C
-	3	Settable	SVCall	System services invoked by SWI directives	0x0000 002C
-	5	Settable	PendSV	System service requests that can be pending	0x0000 0038

6.2 External interrupt/event controller (EXTI)

6.2.1 Introduction

The external interrupt/event controller contains 20 edge detection circuits that generate interrupt/event triggers. Each input line can be independently configured with pulse or pending input types, and three trigger event types including rising edge, falling edge or double edge, which can also be independently shielded. Interrupt requests that hold the state line in the pending register can be cleared by writing '1' in the corresponding bit of the pending register.

6.2.2 Main features

The main features of EXTI controller are as follows:

- Supports 20 software interrupt/event requests
- Interrupts/events corresponding to each input line can be configured to trigger or mask independently
- Each interrupt line has an independent state bit
- Support for pulse or pending input types
- 3 trigger events are supported: rising edge, falling edge, and double edge
- Can wake up to exit low power mode

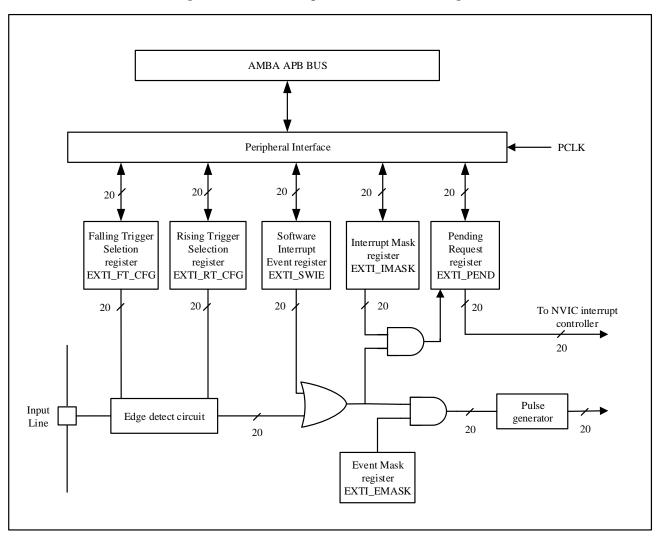

Figure 6-1 Extenal interrupt/event controller block diagram

6.2.3 Functional description

EXTI contains 20 interrupts, 18 from I/O pins and 2 from internal modules. To generate interrupts, the NVIC interrupt channel of the external interrupt controller must be configured to enable the corresponding interrupt line. Select rising edge, falling edge, or double edge trigger event types by edge trigger configuration registers EXTI_RT_CFG and EXTI_FT_CFG, and write '1' to the corresponding bit of interrupt masking register EXTI_IMASK to allow interrupt requests. When a preset edge trigger polarity is detected on the external interrupt line, an interrupt request is generated and the corresponding bit is set to '1'. Writing '1' to the corresponding bit of the pending register clears the interrupt request.

To generate events, the corresponding event line must be configured and enabled. According to the desired edge detection polarity, set up the rise/fall edge trigger configuration register, while writing '1' in the corresponding bit of the event masking register to allow interrupt requests. When a preset edge occurs on an event line, an event request pulse is generated and the corresponding pending bit is not set to '1'.

In addition, interrupt/event requests can also be generated by software by writing a '1' in the software interrupt/event register.

- Hardware interrupt configuration, select and configure 20 lines as interrupt sources as required:
 - Configure the mask bit (EXTI_IMASK) for 20 interrupt lines.
 - Configure the trigger configuration bits for the selected interrupt line(EXTI_RT_CFG and EXTI_FT_CFG);
 - Configure the enable and mask bits of the NVIC interrupt channel corresponding to the external interrupt controller so that the requests in the 20 interrupt lines can be correctly responded.
- Hardware event configuration: Select 20 lines as event sources as required:
 - Configure the mask bit (EXTI_EMASK) for 20 event lines.
 - Configure the trigger configuration bits for the selected event line (EXTI_RT_CFG and EXTI_FT_CFG).
- Software interrupt/event configuration, select 20 lines as software interrupt/event lines as required:
 - Configure 20 interrupt/event line mask bits (EXTI_IMASK and EXTI_EMASK).
 - Configure the request bit of the software interrupt event register (EXTI_SWIE).

6.2.4 EXTI line mapping

To configure external interrupts/events on the GPIO line by AFIO_CFG.EXTI_ETRR[4:0], the AFIO clock must be enabled first. The general-purpose I/O ports and internal modules are connected as follows:

- EXTI line 0 is connected to PA0
- EXTI line 1 is connected to PA1
- EXTI line 2 is connected to PA2
- EXTI line 3 is connected to PA3
- EXTI line 4 is connected to PA4
- EXTI line 5 is connected to PA5
- EXTI line 6 is connected to PA6
- EXTI line 7 is connected to PA7
- EXTI line 8 is connected to PA8
- EXTI line 9 is connected to PA9
- EXTI line 10 is connected to PA10
- EXTI line 11 is connected to PA11
- EXTI line 12 is connected to PA12
- EXTI line 13 is connected to PA13
- EXTI line 14 is connected to PA14
- EXTI line 15 is connected to PA15
- EXTI line 16 is connected to PB0

- EXTI line 17 is connected to PB1
- EXTI line 18 is connected to PVD
- EXTI line 19 is connected to TIM6 wake up event

	This bit is set to '1' when a selected edge trigger event occurs on the external interrupt
	line. It can be cleared by writing '1' to the bit.
	Reserved

7 CRC calculation unit

7.1 CRC introduction

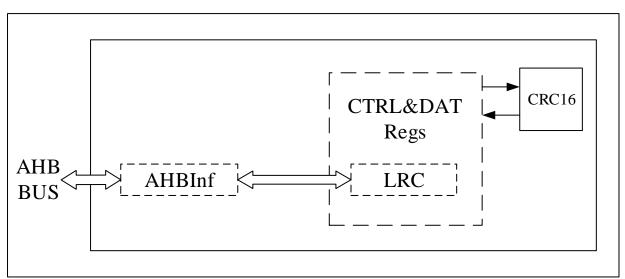

This module integrates the functions of CRC16, and the cyclic redundancy check (CRC) calculation unit obtains any CRC calculation result according to a fixed generator polynomial. In other applications, CRC technology is mainly used to verify the correctness and integrity of data transmission or data storage. CRC calculation unit can calculate the identifier of the software when the program is running, then compare it with the reference identifier generated during connection, and then store it in the specified memory space.

7.2 CRC main features

- CRC16($X^{16}+X^{15}+X^2+1$)
- There are 8 bits of data to be checked and 16 bits of output check code.
- CRC calculation time: 1 AHB clock cycle (HCLK)
- The verification initial value can be configured, and the size end of the data to be verified can be configured.
- Support 8bit LRC check value generation

The following figure is the block diagram of CRC unit.

7.3 CRC function description

CRC_CRC16CTRL.ENDHL controls little endian or big endian.

To clear the result of the last CRC operation, set CRC_CRC16CTRL.CLR to 1 or CRC_CRC16D to 0.

The initial value of CRC calculation can be configured by writing the CRC_CRC16D register. By default, the initial value is the result of the last calculation.

LRC calculation is the same as CRC calculation. Both are carried out at the same time. CRC or LRC can be read out depending on needs. If the initial value needs to be set, the LRC register should be configured first.

7.4 CRC software calculation method

In practical applications, if you need to calculate CRC16 through software to match the hardware calculation results, you need to correctly configure the following:

- WIDTH: 16
- POLY: 0x8005
- INIT: 0x0000
- XOROUT: 0x0000
- REFIN: No
- REFOUT: No

7.5 CRC registers

7.5.1 CRC register overview

The following table lists the registers and reset values of CRC.

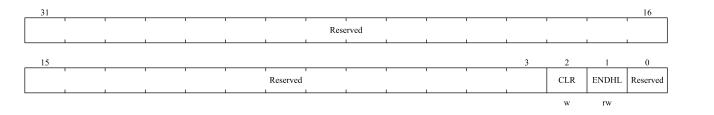

Table 7-1 CRC register overview

Offset	Register	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	6	8	7	9	5	4	3	2	1	0

7.5.2 CRC16 control register (CRC_CRC16CTRL)

Address offset: 0x0C

Reset value: 0x0000 0000

Nations Technologies Inc. Tel: +86-755-86309900 Email: info@nationstech.com Address: Nations Tower, #109 Baoshen Road, Hi-tech Park North. Nanshan District, Shenzhen, 518057, P.R.China

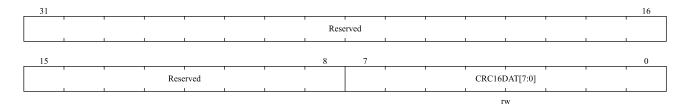

Bit field	Name	Description
31:3	Reserved	Reserved, the reset value must be maintained
2	CLR	Clear CRC16 results.
		0: Not clear.
		1: Clear to default value 0x0000. Set this bit to 1 will only maintain 1 clock cycle, hardware
		will clear automatically. (Software read always 0).
1	ENDHL	Data to be verified start to calculate from MSB or LSB.
		0: From MSB to LSB
		1: From LSB to MSB
		This bit is only for data to be verified.
0	Reserved	Reserved, the reset value must be maintained

Note: 8-bits, 16-bits and 32-bits operations are supported.

7.5.3 CRC16 input data register (CRC_CRC16DAT)

Address offset: 0x10

Reset value: 0x0000 0000

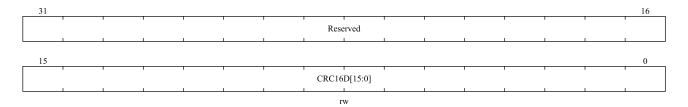

Bit field	Name	Description
31:8	Reserved	Reserved, the reset value must be maintained
7:0	CRC16DAT[7:0]	Data to be verified.

Note: 8-bits, 16-bits and 32-bits operations are supported.

7.5.4 CRC cyclic redundancy check code register (CRC_CRC16D)

Address offset: 0x14

Reset value: 0x0000 0000

 Bit field
 Name
 Description

 31:16
 Reserved
 Reserved, the reset value must be maintained

Bit field	Name	Description
15:0	CRC16D[15:0]	16-bit value of cyclic redundancy result data.
		Every time the software writes the CRC16DAT register, the 16-bit calculated data from
		CRC16 is updated in this register.

Note: 8-bits, 16-bits and 32-bits operations are supported (8-bit operations must be performed twice in a row to ensure that 16-bit initial values are configured properly)

7.5.5 LRC result register (CRC_LRC)

Address offset: 0x18

Reset value: 0x0000 0000

31		 			 							 16
					Rese	erved	•	•		I		
	I	 LI		LI	I	I	I	I	I	I	I	
15					8	7						0
		Rese	rved						LRCD.	AT[7:0]		
		 		· · · · · · · · ·					r	w		

Bit field	Name	Description
31:8	Reserved	Reserved, the reset value must be maintained
7:0	LRCDAT[7:0]	LRC check value register.
		Software need to write initial value before use. And then each time data written to
		CRC_CRC16DAT is "XOR" with the value of the CRC_LCR register. The result will be
		stored in CRC_LCR. Software read the result. It should be cleared before next use.

8 Advanced-control timers (TIM1)

8.1 TIM1 introduction

The advanced control timers (TIM1) is mainly used in the following occasions: counting the input signal, measuring the pulse width of the input signal and generating the output waveform, etc.

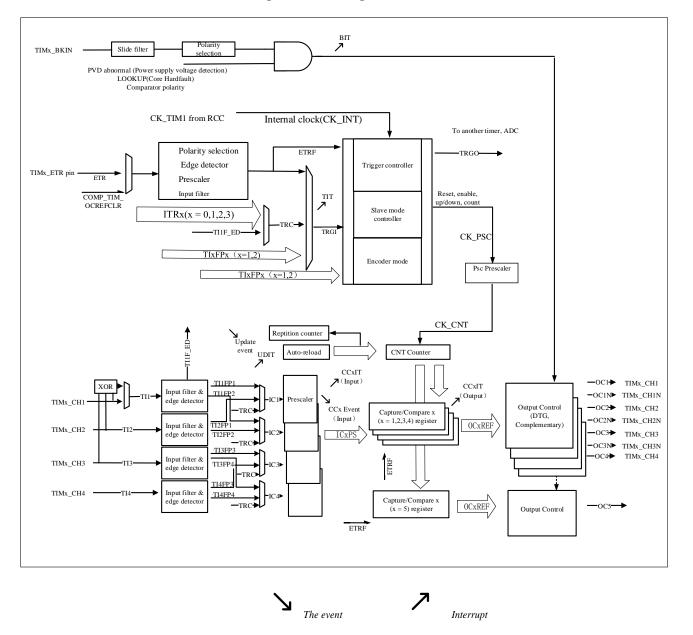

Advanced timers have complementary output function with dead-time insertion and break function. Suitable for motor control.

8.2 Main features of TIM1

- 16-bit auto-reload counters. (It can realize up-counting, down-counting, up/down counting)
- 16-bit programmable prescaler. (The frequency division factor can be configured with any value between 1 and 65536)
- Programmable Repetition Counter
- TIM1 up to 5 channels.
- 4 capture/compare channels, the working modes are PWM output, ouput compare, one-pulse mode output, input capture.
- The events that generate the interrupt are as follows:
 - Update event
 - Trigger event
 - Input capture
 - Output compare
 - Break input
- Complementary outputs with adjustable dead-time
 - For TIM1, channel 1,2,3 support this feature
- Timer can be controlled by external signal
- Timers are linked internally for timer synchronization or chaining
- TIM1_CC5 for COMP blanking

Figure 8-1 Block diagram of TIM1

The capture channel 1 input can come from IOM or comparator output

8.3 TIM1 function description

8.3.1 **Time-base unit**

The advanced-control's time-base unit mainly includes: prescaler, counter, auto-reload and repetition counter. When the time base unit is working, the software can read and write the corresponding registers (TIMx_PSC, TIMx_CNT, TIMx_AR and TIMx_REPCNT) at any time.

Depending on the setting of the auto-reload preload enable bit (TIMx_CTRL1.ARPEN), the value of the preload register is transferred to the shadow register immediately or at each update event UEV. An update event is generated when the counter reaches the overflow/underflow condition and it can be generated by software when

TIMx_CTRL1.UPDIS=0. The counter CK_CNT is valid only when the TIMx_CTRL1.CNTEN bit is set. The counter starts counting one clock cycle after the TIMx_CTRL1.CNTEN bit is set.

8.3.1.1 **Prescaler description**

The TIMx_PSC register consists of a 16-bit counter that can be used to divide the counter clock frequency by any factor between 1 and 65536. It can be changed on the fly as it is buffered. The prescaler value is only taken into account at the next update event.

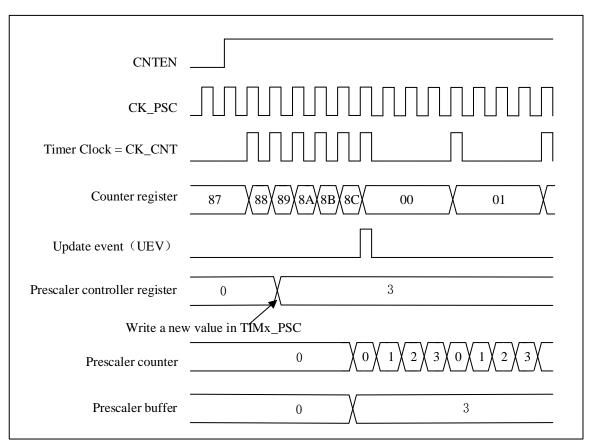

Figure 8-2 Counter timing diagram with prescaler division change from 1 to 4

8.3.2 Counter mode

8.3.2.1 Up-counting mode

In up-counting mode, the counter will count from 0 to the value of the register TIMx_AR, then it resets to 0. And a counter overflow event is generated.

If the TIMx_CTRL1.UPRS bit (select update request) and the TIMx_EVTGEN.UDGN bit are set, an update event (UEV) will generate. And TIMx_STS.UDITF will not be set by hardware, therefore, no update interrupts are generated. This setting is used in scenarios where you want to clear the counter but do not want to generate an update interrupt.

Depending on the update request source is configured in the TIMx_CTRL1.UPRS, When an update event occurs, all registers are updated and the TIMx_STS.UDITF is set:

■ The repetition counter reloads the contents of the TIMx_REPCNT

- Update auto-reload shadow registers with preload value(TIMx_AR), when TIMx_CTRL1.ARPEN = 1.
- The prescaler shadow register is reloaded with the preload value(TIMx_PSC).

To avoid updating the shadow registers when new values are written to the preload registers, you can disable the update by setting TIMx_CTRL1.UPDIS=1.

When an update event occurs, the counter will still be cleared and the prescaler counter will also be set to 0 (but the prescaler value will remain unchanged).

The figure below shows some examples of the counter behavior and the update flags for different division factors in the up-counting mode.

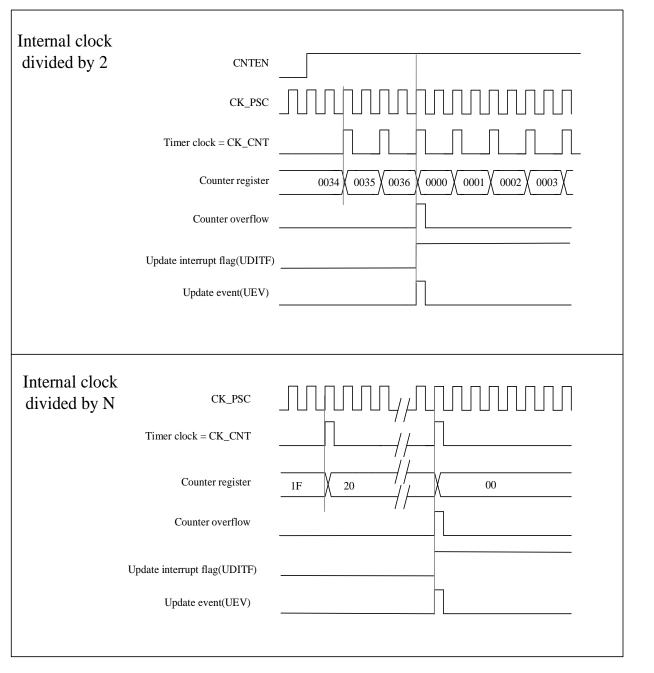

Figure 8-3 Timing diagram of up-counting. The internal clock divider factor = 2/N

Nations Technologies Inc. Tel: +86-755-86309900 Email: info@nationstech.com Address: Nations Tower, #109 Baoshen Road, Hi-tech Park North. Nanshan District, Shenzhen, 518057, P.R.China

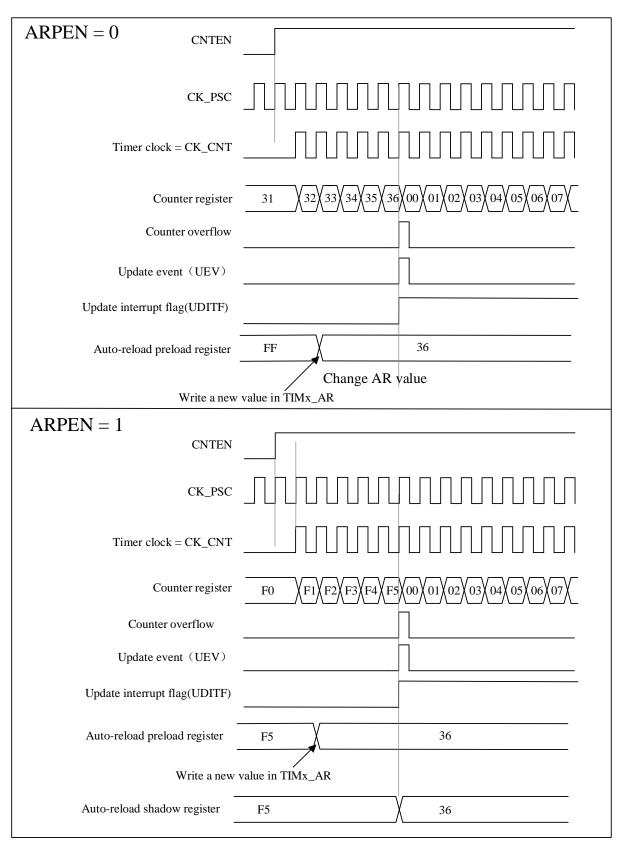

Figure 8-4 Timing diagram of the up-counting, update event when ARPEN=0/1

Nations Technologies Inc. Tel: +86-755-86309900 Email: info@nationstech.com Address: Nations Tower, #109 Baoshen Road, Hi-tech Park North. Nanshan District, Shenzhen, 518057, P.R.China

8.3.2.2 **Down-counting mode**

In down-counting mode, the counter will decrement from the value of the register TIMx_AR to 0, then restart from the auto-reload value and generate a counter underflow event.

The process of configuring update events and updating registers in down-counting mode is the same as in up-counting mode, see 8.3.2.1.

The figure below shows some examples of the counter behavior and the update flags for different division factors in the down-counting mode.

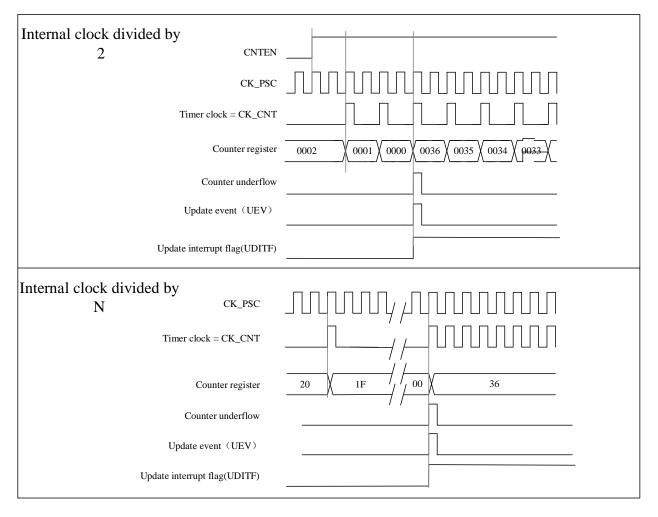

Figure 8-5 Timing diagram of the down-counting, internal clock divided factor = 2/N

8.3.2.3 Center-aligned mode

In center-aligned mode, the counter increments from 0 to the value $(TIMx_AR) - 1$, a counter overflow event is generated. It then counts down from the auto-reload value $(TIMx_AR)$ to 1 and generates a counter underflow event. Then the counter resets to 0 and starts counting up again.

In this mode, the TIMx_CTRL1.DIR direction bits have no effect and the count direction is updated and specified by hardware. Center-aligned mode is valid when the TIMx_CTRL1. CAMSEL bit is not equal to "00".

The update events can be generated each time the counter overflows and each time the counter underflows. Alternatively, an update event can also be generated by setting the TIMx_EVTGEN. UDGN bit (either by software

or using a slave mode controller). In this case, the counter restarts from 0, as does the prescaler's counter.

Please note: if the update source is a counter overflow, auto-reload update before reloading the counter.

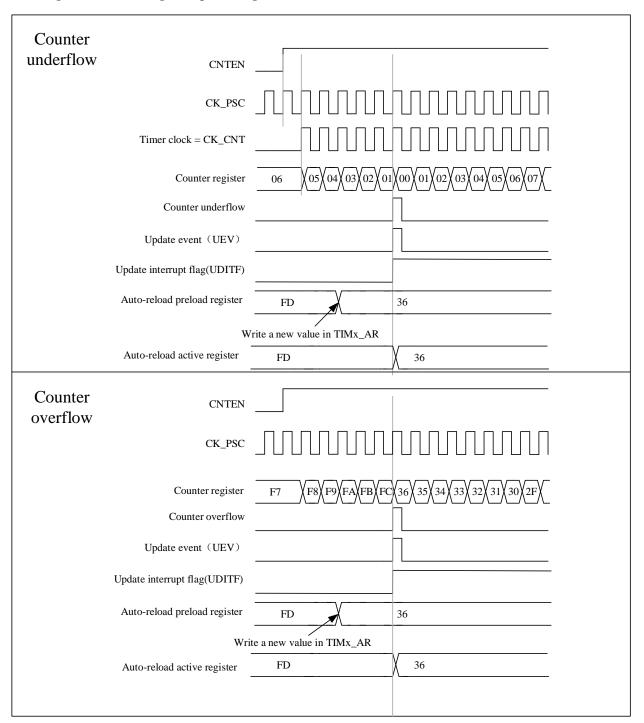

Figure 8-7 A center-aligned sequence diagram that includes counter overflows and underflows (ARPEN = 1)

8.3.3 Repetition counter

The basic unit of Section 8.3.1 describes the conditions for generating an update event (UEV). An update event (UEV) is actually only generated when the repeat counter reaches zero, which is valuable for generating PWM signals.

This means that data is transferred from the preload registers to the shadow registers every N+1 counter overflow or underflow, where N is the value in the TIMx_REPCNT.

The repetition counter is decremented:

- In the up-counting mode, each time the counter reaches the maximum value, an overflow occurs.
- In down-counting mode, each time the counter decrements to the minimum value, an underflow occurs.
- In center-aligned mode, each time the counter overflows or underflows.

Its repetition rate is defined by the value of the TIMx_REPCNT register.

Repetition counters feature automatic reloading. The update event (generated by setting TIMx_EVTGEN.UDGN or hardware through slave mode controller) occurs immediately, regardless of the value of the repeat counter.

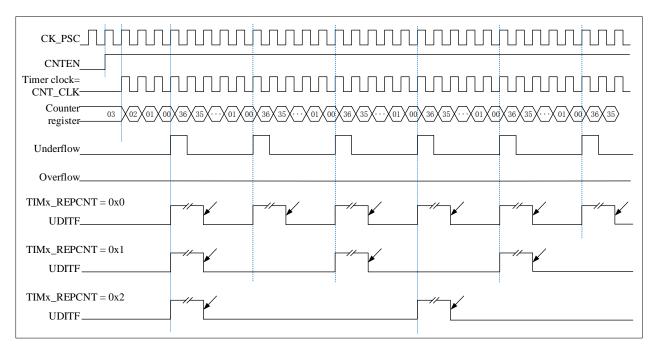

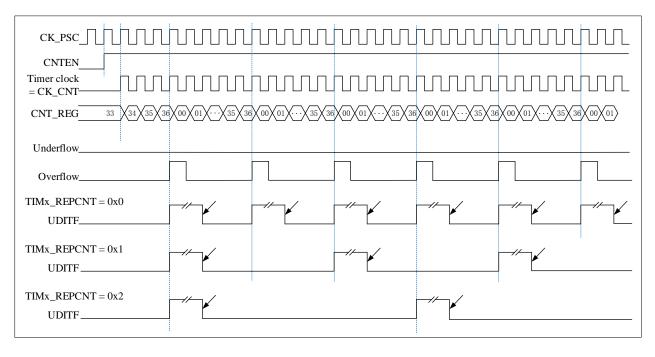

Figure 8-8 Repeat count sequence diagram in down-counting mode

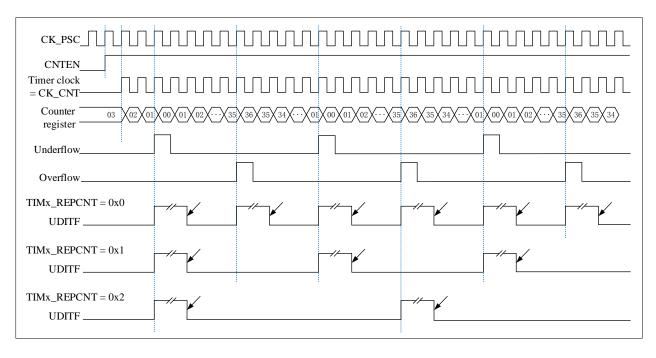

Software clear

Figure 8-10 Repeat count sequence diagram in center-aligned mode

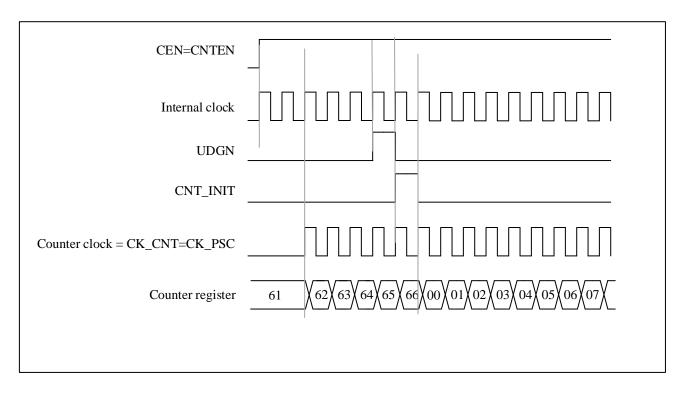

8.3.4 Clock selection

- The internal clock of Advanced-control timers : CK_INT
- Two kinds of external clock mode :
 - external input pin
 - external trigger input ETR
- Internal trigger input (ITRx): one timer is used as a prescaler for another timer.

8.3.4.1 Internal clock source (CK_INT)

When the TIMx_SMCTRL.SMSEL is equal to "000", the slave mode controller is disabled. The three control bits (TIMx_CTRL1.CNTEN、TIMx_CTRL1.DIR、TIMx_EVTGEN.UDGN) can only be changed by software (except TIMx_EVTGEN.UDGN, which remains cleared automatically). It is provided that the TIMx_CTRL1.CNTEN bit is written as' 1 ' by soft, the clock source of the prescaler is provided by the internal clock CK_INT.

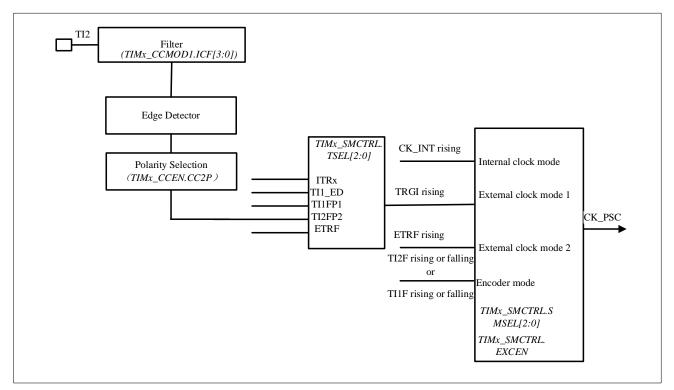

Figure 8-11 Control circuit in normal mode, internal clock divided by 1

8.3.4.2 External clock source mode 1

This mode is selected by configuring TIMx_SMCTRL.SMSEL=111. The counter can be configured to count on the rising or falling edge of the clock at the selected input.

For example, to configure up-counting mode to count on the rising edge of the clock at the TI2 input, the configuration steps are as follows:

- Configure TIMx_CCMOD1.CC2SEL equal to '01', CC2 channel is configured as input, IC2 is mapped to TI2
- Configure TIMx_CCEN.CC2P equal to '0', select clock rising edge polarity
- To select input filter bandwidth by configuring TIMx_CCMOD1.IC2F[3:0] (if filter is not needed, keep IC2F bit at '0000')
- Configure TIMx_SMCTRL.SMSEL equal to '111', select timer external clock mode 1
- Configure TIMx_SMCTRL.TSEL equal to '110', select TI2 as the trigger input source
- Configure TIMx_CTRL1.CNTEN equal to '1' to start the counter

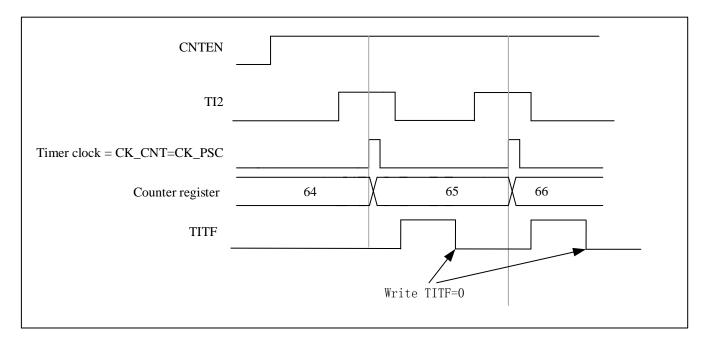

Note: The capture prescaler is not used for triggering, so it does not need to be configured

When the rising edge of the timer clock occurs at TI2=1, the counter counts once and the TIMx_STS .TITF flag is pulled high.

The delay between the rising edge of TI2 and the actual clock of the counter depends on the resynchronization circuit at the input of TI2.

Figure 8-13 Control circuit in external clock mode 1

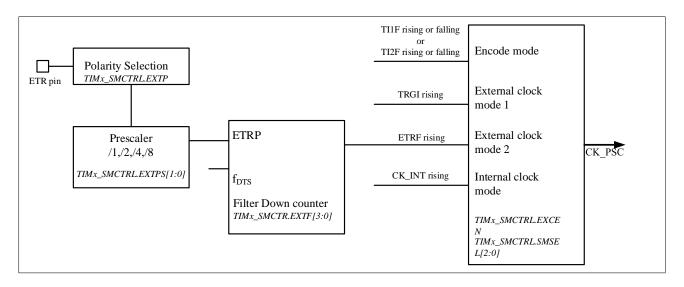

8.3.4.3 External clock source mode 2

This mode is selected by TIMx_SMCTRL.EXCEN equal to 1. The counter can count on every rising or falling edge of the external trigger input ETR.

The following figure is a schematic diagram of the external trigger input module in External clock source mode 2

Figure 8-14 External trigger input block diagram

For example, use the following configuration steps to make the up counter count every 2 rising edges on ETR.

- Since no filter is needed in this case, make TIMx_SMCTRL .EXTF[3:0] equal to '0000'
- Configure the prescaler by making TIMx_SMCTRL.EXTPS[1:0] equal to '01'
- Select the polarity on ETR pin by setting TIMx_SMCTRL.EXTP equal to '0', The rising edge of ETR is valid

122 / 319

- External clock mode 2 is selected by setting TIMx_SMCTRL .EXCEN equal to '1'
- Turn on the counter by setting TIMx_CTRL1. CNTEN equal to '1'

The counter counts every 2 rising edges of ETR. The delay between the rising edge of ETR and the actual clock to the counter is due to a resynchronization circuit on the ETRP signal.

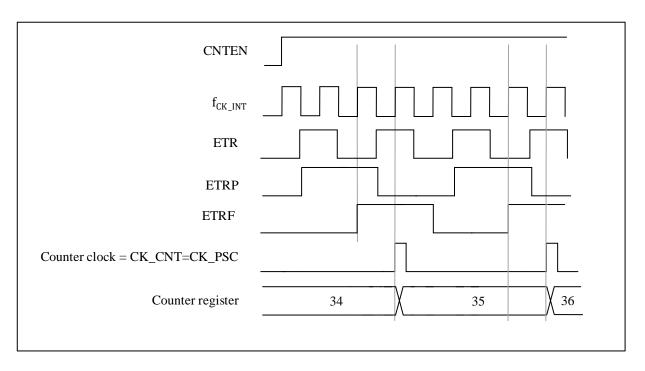

Figure 8-15 Control circuit in external clock mode 2

8.3.5 Capture/compare channels

Capture/compare channels include capture/compare registers and shadow registers. The input section consists of digital filters, multiplexers and prescalers. The output section includes comparators and output controls.

The input signal TIx is sampled and filtered to generate the signal TIxF. A signal (TIxF_rising or TIxF_falling) is then generated by the edge detector of the polarity select function, the polarity of which is selected by the TIMx_CCEN.CCxP bits. This signal can be used as a trigger input for the slave mode controller. At the same time, the signal ICx is sent to the capture register after frequency division. The following figure shows a block diagram of a capture/compare channel.

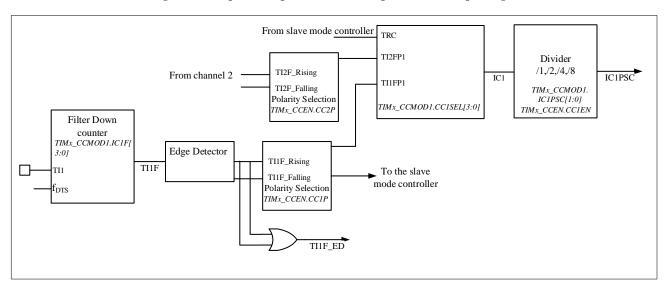

Figure 8-16 Capture/compare channel (example: channel 1 input stage)

The output part generates an intermediate waveform OCxRef (active high) as reference. The polarity acts at the end of the chain.

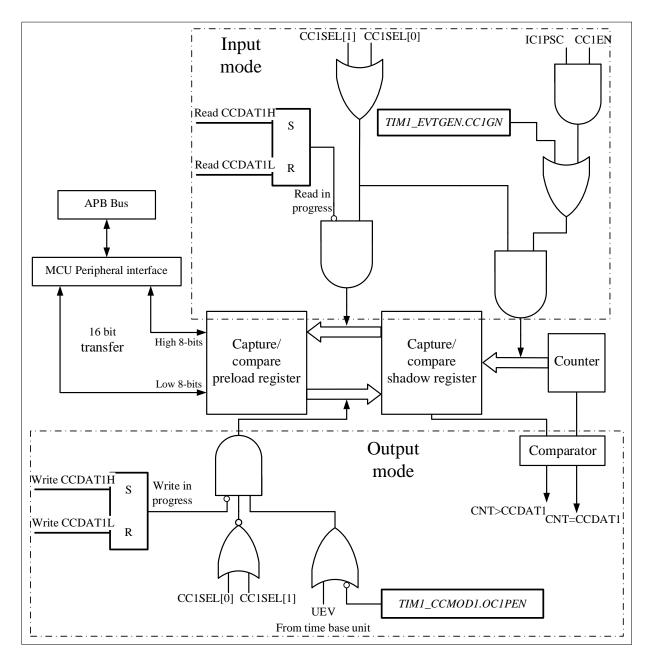

Figure 8-17 Capture/compare channel 1 main circuit

Figure 8-18 Output part of channelx (x= 1,2,3, take channel 1 as example)

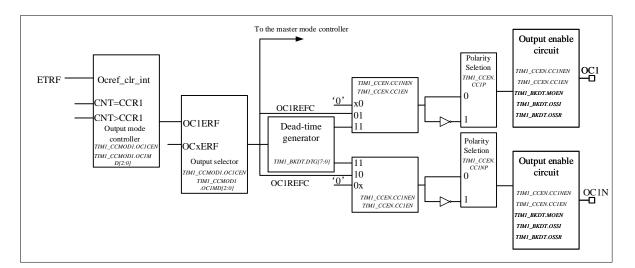

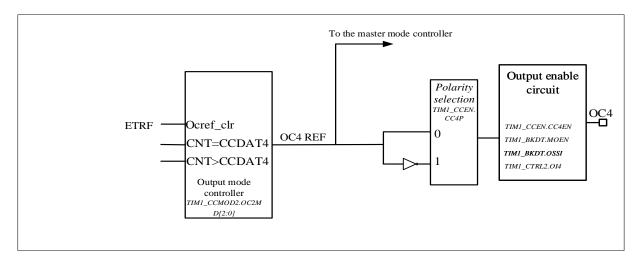

Figure 8-19 Output part of channelx (x= 4)

Reads and writes always access preloaded registers when capturing/comparing. The two specific working processes are as follows:

In capture mode, the capture is actually done in the shadow register, and then the value in the shadow register is copied into the preload register.

In compare mode, as opposed to capture mode, the value of the preload register is copied into the shadow register, which is compared with the counter.

8.3.6 **Input capture mode**

In capture mode, the TIMx_CCDATx registers are used to latch the counter value after the ICx signal detects.

There is a capture interrupt flag TIMx_STS.CCxITF, which can issue an interrupt if the corresponding interrupt enable is pulled high.

The TIMx_STS. CCxITF bit is set by hardware when a capture event occurs and is cleared by software or by reading the TIMx_CCDATx register.

The overcapture flag TIMx_STS.CCxOCF is set equal to 1 when the counter value is captured in the TIMx_CCDATx register and TIMx_STS.CC1ITF is already pulled high. Unlike the former, TIMx_STS.CCxOCF is cleared by writing 0 to it.

To achieve a rising edge of the TI1 input to capture the counter value into the TIMx_CCDAT1 register, the configuration flow is as follows:

To select a valid input:

Configure TIMx_CCMOD1.CC1SEL to '01'. At this time, the input is the CC1 channel, and IC1 is mapped to TI1.

■ Program the desired input filter duration:

Define the sampling frequency of the TI1 input and the length of the digital filter by configuring the TIMx_CCMODx.ICxF bits. Example: If the input signal jitters up to 5 internal clock cycles, we must choose a filter duration longer than these 5 clock cycles. When 8 consecutive samples (sampled at f_{DTS} frequency) with the new level are detected, we can validate the transition on TI1. Then configure TIMx_CCMOD1. IC1F to '0011'.

- By configuring TIMx_CCEN .CC1P=0, select the rising edge as the valid transition polarity on the TI1 channel.
- Configure the input prescaler. In this example, configure TIMx_CCMOD1.IC1PSC= '00' to disable the prescaler because we want to capture every valid transition.
- Enable capture by configuring TIMx_CCEN. CC1EN = '1'.

If you want enable related interrupt request, you can configureTIMx_DINTEN.CC1IEN bit=1

8.3.7 **PWM input mode**

There are some differences between PWM input mode and normal input capture mode, including:

- Two ICx signals are mapped to the same TIx input.
- The two ICx signals are active on edges of opposite polarity.
- Select one of two TIxFP signals as trigger input.
- The slave mode controller is configured in reset mode.

For example, the following configuration flow can be used to know the period and duty cycle of the PWM signal on TI1 (It depends on the frequency of CK_INT and the value of the prescaler).

- Configure TIMx_CCMOD1.CC1SEL equal to '01' to select TI1 as valid input for TIMx_CCDAT1.
- Configure TIMx_CCEN.CC1P equal to '0' to select the active polarity of filtered timer input 1(TI1FP1), valid on the rising edge.
- Configure TIMx_CCMOD1.CC2SEL equal to '10' select TI1 as valid input for TIMx_CCDAT2.
- Configure TIMx_CCEN.CC2P equal to 1 to select the valid polarity of filtered timer input 2(TI1FP2), valid on the falling edge.
- Configure TIMx_SMCTRL.TSEL=101 to select Filtered timer input 1 (TI1FP1) as valid trigger input.

127 / 319

- Configure TIMx_SMCTRL.SMSEL=100 to configure the slave mode controller to reset mode.
- Configure TIMx_CCEN. CC1EN=1 and TIMx_CCEN.CC2EN=1 to enable capture.

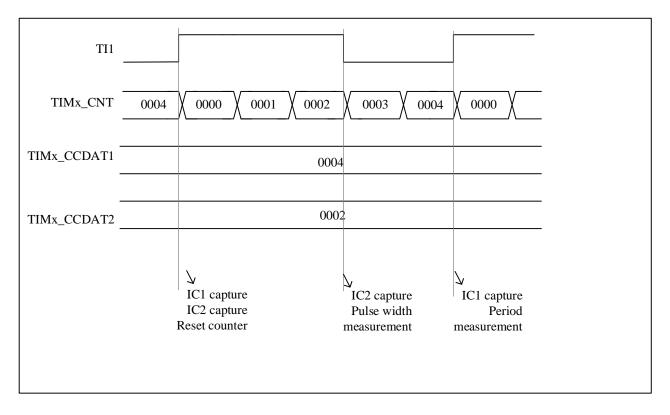

Figure 8-20 PWM input mode timing

Because of only filter timer input 1 (TI1FP1) and filter timer input 2 (TI2FP2) are connected to the slave mode controller, the PWM input mode can only be used with the TIMx_CH1/TIMx_CH2 signals.

8.3.8 Forced output mode

Software can force output compare signals to active or inactive level directly, in output mode (TIMx_CCMODx.CCxSEL=00).

User can set TIMx_CCMODx. OCxMD=101 to force the output compare signal to active level. And the OCxREF will be forced high, OCx get opposite value to CCxP polarity bit. On the other hand, user can set TIMx_CCMODx. OCxMD=100 to force the output compare signal to inactive level.

The values of the TIMx_CCDATx shadow register and the counter still comparing with each other in this mode.

The comparison between the output compare register TIMx_CCDATx and the counter TIMx_CNT has no effect on OCxREF. And the flag still can be set. Therefore, the interrupt still can be sent.

8.3.9 **Output compare mode**

User can use this mode to control the output waveform, or to indicate that a period of time has elapsed.

When the capture/compare register and the counter have the same value, the output compare function's operations are as follow:

- TIMx_CCMODx.OCxMD is for output compare mode, and TIMx_CCEN.CCxP is for output polarity. When the compare matches, if set TIMx_CCMODx.OCxMD=000, the output pin will keep its level; if set TIMx_CCMODx.OCxMD=001, the output pin will be set active; if set TIMx_CCMODx.OCxMD=010, the output pin will be set inactive; if set TIMx_CCMODx.OCxMD=011, the output pin will be set to toggle.
- Set TIMx_STS.CCxITF.
- If user set TIMx_DINTEN.CCxIEN, a corresponding interrupt will be generated.

User can set TIMx_CCMODx.OCxPEN to choose capture/compare shawdow register using capture/compare preload registers(TIMx_CCDATx) or not.

The time resolution is one count of the counter.

In one-pulse mode, the output compare mode can also be used to output a single pulse.

Here are the configuration steps for output compare mode:

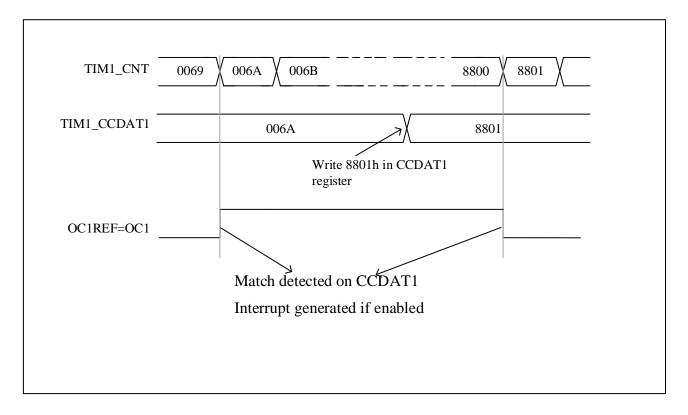

- First of all, user should select the counter clock.
- Secondly, set TIMx_AR and TIMx_CCDATx with desired data.
- If user need to generate an interrupt, set TIMx_DINTEN.CCxIEN.
- Then select the output mode by set TIMx_CCEN.CCxP, TIMx_CCMODx.OCxMD, TIMx_CCEN.CCxEN, etc.
- At last, set TIMx_CTRL1.CNTEN to enable the counter.

User can update the output waveform by setting TIMx_CCDATx at any time, as long as the preload register is not enabled. Otherwise the TIMx_CCDATx shadow register will be updated at the next update event.

Here is an example.

8.3.10 **PWM mode**

User can use PWM mode to generate a signal whose duty cycle is determined by the value of the TIMx_CCDATx register and whose frequency is determined by the value of the TIMx_AR register. And depends on the value of TIMx_CTRL1.CAMSEL, the TIM can generate PWM signal in edge-aligned mode or center-aligned mode.

User can set PWM mode 1 or PWM mode 2 by setting TIMx_CCMODx. OCxMD=110 or setting TIMx_CCMODx. OCxMD=111. To enable preload register, user must set corresponding TIMx_CCMODx.OCxPEN. And then set TIMx_CTRL1.ARPEN to auto-reload preload register eventually.

User can set polarity of OCx by setting TIMx_CCEN.CCxP. On the other hand, to enable the output of OCx, user need to set the combination of the value of CCxEN, CCxNEN, MOEN, OSSI, and OSSR in TIMx_CCEN and TIMx_BKDT.

The values of TIMx_CNT and TIMx_CCDATx are always compared with each other when the TIM is under PWM mode.

Only if an update event occurs, the preload register will transfer to the shadow register. Therefore user must reset all the registers by setting TIMx_EVTGEN.UDGN before the counter starts counting..

8.3.10.1 **PWM center-aligned mode**

If user set TIMx_CTRL1.CAMSEL equal 01, 10 or 11, the PWM center-aligned mode will be active. The setting of the compare flag depends on the value of TIMx_CTRL1.CAMSEL. There are three kinds of situation that the compare flag is set, only when the counter counts up, only when the counter counts down, or when the counter counts up and counts down. User should not modified TIMx_CTRL1.DIR by software, it is updated by hardware.

Examples of center-aligned PWM waveforms is as follow, and the setting of the waveform are: TIMx_AR=8, PWM mode 1, the compare flag is set when the counter counts down corresponding to TIMx_CTRL1. CAMSEL=01.

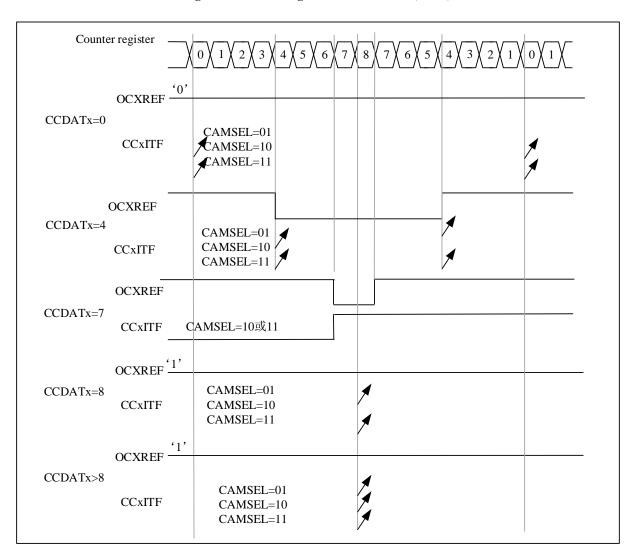

Figure 8-22 Center-aligned PWM waveform (AR=8)

Notes that user should know when using center-aligned mode are as follow:

- It depends on the value of TIMx_CTRL1.DIR that the counter counts up or down. Cautions that the DIR and CAMSEL bits should not be changed at the same time.
- User should not write the counter while running in center-aligned mode, otherwise it will cause unexpected results. Here are some example:
 - If the value written into the counter is 0 or is the value of TIMx_AR, the direction will be updated but the update event will not be generated.
 - If the value written into the counter is greater than the value of auto-reload, the direction will not be updated.
- To be on the safe side, user is suggested setting TIMx_EVTGEN.UDGN to generate an update by software before starting the counter, and not writing the counter while it is running.

8.3.10.2 PWM edge-aligned mode

There are two kinds of configuration in edge-aligned mode, up-counting and down-counting.

• Up-counting

User can set TIMx_CTRL1.DIR=0 to make counter counts up.

Here is an example for PWM mode1.

When TIMx_CNT < TIMx_CCDATx, the reference PWM signal OCxREF is high. Otherwise it will be low. If the compare value in TIMx_CCDATx is greater than the auto-reload value, the OCxREF will remains 1. Conversely, if the compare value is 0, the OCxREF will remains 0.

When TIMx_AR=8, the PWM waveforms are as follow.

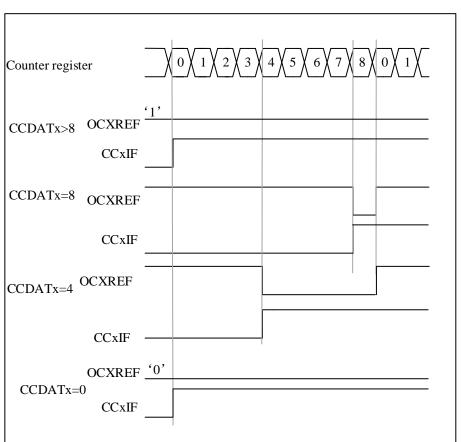

Figure 8-23 Edge-aligned PWM waveform (APR=8)

• Down-counting

User can set TIMx_CTRL1.DIR=1 to make counter counts down.

Here is an example for PWM mode1.

When $TIMx_CNT > TIMx_CCDATx$, the reference PWM signal OCxREF is low. Otherwise it will be high. If the compare value in $TIMx_CCDATx$ is greater than the auto-reload value, the OCxREF will remains 1.

Note: If the nth PWM cycle CCDATx shadow register >= AR value, the shadow register value of CCDATx in the (n+1)th PWM cycle is 0. At the moment when the counter is 0 in the (n+1)th PWM cycle, although the value of the

132 / 319

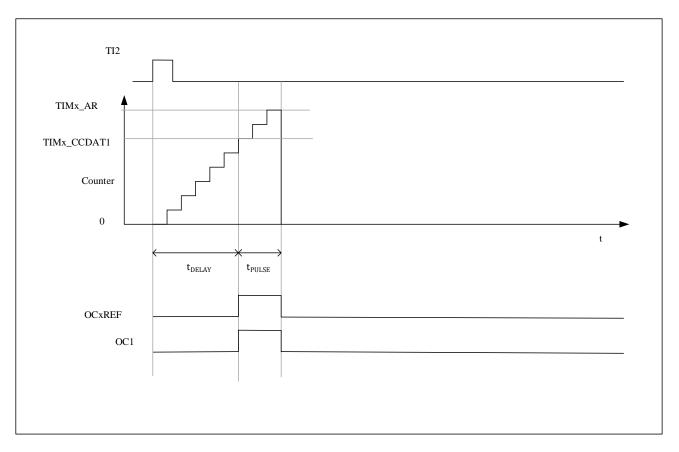

counter = CCDATx shadow register = 0 and OCxREF = '0', no compare event will be generated.

8.3.11 One-pulse mode

In the one-pulse mode (ONEPM), a trigger signal is received, and a pulse t_{PULSE} with a controllable pulse width is generated after a controllable delay t_{DELAY} . The output mode needs to be configured as output compare mode or PWM mode. After selecting one-pulse mode, the counter will stop counting after the update event UEV is generated.

The following is an example of a one-pulse mode:

A rising edge trigger is detected from the TI2 input, and a pulse with a width of t_{PULSE} is generated on OC1 after a delay of t_{DELAY} .

1. Counter configuration: count up, counter $TIMx_CNT < TIMx_CCDAT1 \le TIMx_AR$;

2. TI2FP2 is mapped to TI2, TIMx_CCMOD1.CC2SEL= '01'; TI2FP2 is configured for rising edge detection, TIMx_CCEN.CC2P= '0';

3. TI2FP2 acts as the trigger (TRGI) of the slave mode controller and starts the counter, TIMx_SMCTRL.TSEL= '110', TIMx_SMCTRL.SMSEL= '110' (trigger mode);

4. TIMx_CCDAT1 writes the count value to be delayed (t_{DELAY}), TIMx_AR - TIMx_CCDAT1 is the count value of the pulse width t_{PULSE};

5. Configure TIMx_CTRL1.ONEPM=1 to enable single pulse mode, configure TIMx_CCMOD1.OC1MD = '111'to

133 / 319

select PWM2 mode;

6. Wait for an external trigger event on TI2, and a one pulse waveform will be output on OC1;

8.3.11.1 Special case: OCx fast enable:

In one-pulse mode, an edge is detected through the TIx input, and triggers the start of the counter to count to the comparison value and then output a pulse. These operations limit the minimum delay t_{DELAY} that can be achieved.

You can set TIMx_CCMODx.OCxFEN=1 to turn on OCx fast enable, after triggering the rising edge, the OCxREF signal will be forced to be converted to the same level as the comparison match occurs immediately, regardless of the comparison result. OCxFEN fast enable only takes effect when the channel mode is configured for PWM1 and PWM2 modes.

8.3.12 Clearing the OCxREF signal on an external event

If user set TIMx_CCMODx.OCxCEN=1, high level of ETRF input can be used to driven the OCxREF signal to low, and the OCxREF signal will remains low, until the next UEV happens. Only output compare and PWM modes can use this function. This cannot be used when it is in forced mode.

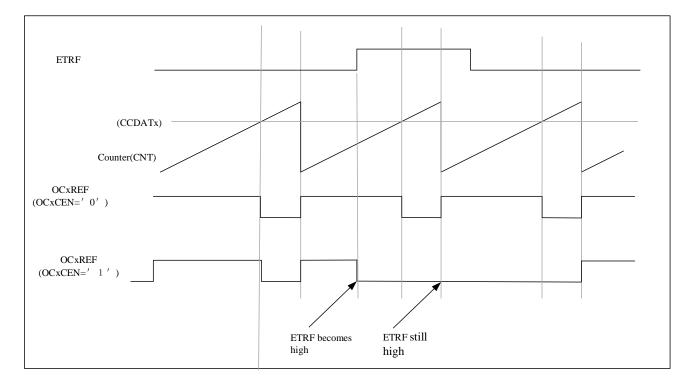

Here is an example for it. To control the current, user can connect the ETR signal to the output of a comparator, and the operation for ETR should be as follow:

- Set TIMx_SMCTRL.EXTPS=00 to disable the external trigger prescaler.
- Set TIMx_SMCTRL.EXCEN=0 to disable the external clock mode 2.
- Set TIMx_SMCTRL.EXTP and TIMx_SMCTRL.EXTF to configure the external trigger polarity and external trigger filter according to the need.

Here is an example for the case that when ETRF input becomes high, the behavior of OCxREF signal for different value of OCxCEN. Timer is set to be in PWM mode in this case.

Figure 8-25 Clearing the OCxREF of TIMx

8.3.13 Complementary outputs with dead-time insertion

Advanced-control timer can output two complementary signals, and manage the switching-off and switching-on of outputs. This is called dead-time. User should adjust dead-time depending on the devices connected to the outputs and their characteristics.

User can select the polarity of outputs by setting TIMx_CCEN.CCxP and TIMx_CCEN.CCxNP. And this selection is independently for each output.

User can control the complementary signals OCx and OCxN by setting the combination of several control bits, which are TIMx_CCEN.CCxEN, TIMx_CCEN.CCxNEN, TIMx_BKDT.MOEN, TIMx_CTRL2.OIx, TIMx_CTRL2.OIxN, TIMx_BKDT.OSSI, and TIMx_BKDT.OSSR. When switching to the IDLE state, the dead-time will be activated.

If user set TIMx_CCEN.CCxEN and TIMx_CCEN.CCxNEN at the same time, a dead-time will be insert. If there is a break circuit, the TIMx_BKDT.MOEN should be set too. There are 10-bit dead-time generators for each channel.

Reference waveform OCxREF can generates 2 outputs OCx and OCxN. And if OCx and OCxN are active high, the OCx ouput signal is the same as the reference signal and the OCxN output signal is the opposite of the reference signal. However, OCx output signal will be delayed relative to the reference rising edge and the OCxN output signal will be delayed relative to the reference falling edge. If the delay is greater than the width of the active OCx or OCxN output, the corresponding pulse will not generated.

The relationships between the output signals of the dead-time generator and the reference signal OCxREF are as follow.

Assume that TIMx_CCEN.CCxP=0, TIMx_CCEN.CCxNP=0, TIMx_BKDT.MOEN=1, TIMx_CCEN.CCxEN=1,

TIMx_CCEN.CCxNEN=1.

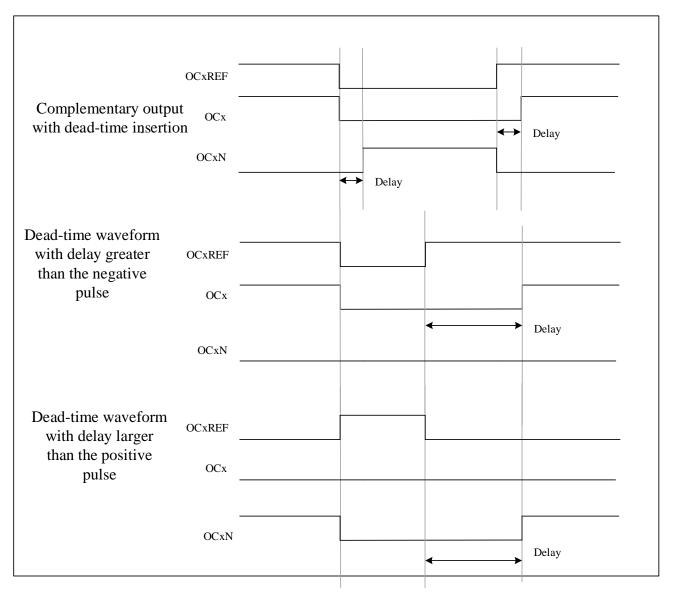

Figure 8-26 Complementary output with dead-time insertion

User can set TIMx_BKDT.DTGN to programme the dead-time delay for each of the channels.

8.3.13.1 Redirecting OCxREF to OCx or OCxN

User can set TIMx_CCEN.CCxEN and TIMx_CCEN.CCxNEN to re-directed OCxREF to the OCx output or to OCxN output, in output mode.

Here are two ways to use this function. When the complementary remains at its inactive level, user can use this function to send a specific waveform, such as PWM or static active level. User can also use this function to set both outputs in their inactive level or both outputs active and complementary with dead-time.

If user set TIMx_CCEN.CCxEN=0 and TIMx_CCEN.CCxNEN=1, it will not complemented, and OCxN will become active when OCxREF is high. On the other hand, if user set TIMx_CCEN.CCxEN=1 and TIMx_CCEN.CCxNEN=1, OCx will become active when OCxREF is high. On the contrary, OCxN will become active when OCxREF is high.

8.3.14 Break function

The output enable signals and inactive levels will be modified when setting the corresponding control bits when using the break function. However, the output of OCx and OCxN cannot at the active level at the same time no matter when, that is, $(CCxP^OIx)^{(CCxNP^OIx)!=0}$.

When multiple break signals are enabled, each break signal constitutes an OR logic. Here are some signal which can be the source of breaking.

- The break input pin
- A PVD failure event.
- Core Hardfault event.
- The output signal of the comparator (configured in the comparator module, high level break).
- By software through the TIMx_EVTGEN.BGN.

The break circuit will be disable after reset. And the MOEN bit will be low. User can set TIMx_BKDT.BKEN to enable the break function. The polarity of break input signal can be selected by setting TIMx_BKDT.BKP. User can modify the TIMx_BKDT.BKEN and TIMx_BKDT.BKP at the same time. After user set the TIMx_BKDT.BKEN and TIMx_BKDT.BKP, there is 1 APB clock cycle delay before the option take effect. Therefore, user need to wait 1 APB clock cycle to read back the value of the written bit.

The falling edge of MOEN can be asynchronous, so between the actual signal and the synchronous control bit, there set a resynchronization circuit. This circuit will cause a delay between the asynchronous and the synchronous signal. When user set TIMx_BKDT.MOEN while it is low, user need to insert a delay before reading the value. Because an asynchronous signal was written but user read the synchronous signal.

The behaviors that after a break occurs are as follow:

- TIMx_BKDT.MOEN will be cleared asynchronously, and then the outputs will be put in inactive state, idle state or reset state. The state of output is selected by setting TIMx_BKDT.OSSI. This will take effect even if the MCU oscillator is off.
- Once TIMx_BKDT.MOEN=0, the output of each output channel will be driven with the level programmed in TIMx_CTRL2.OIx. Timer will release the enable outputs(taken over by GPIO controller) if TIMx_BKDT.OSSI=0, otherwise it will remains high.
- If user choose to use complementary outputs, the behaviors of TIM are as follow
 - Depends on the polarity, the outputs will be set in reset state first. It is an asynchronous option so it still works even if there is no clock provided to the timer.
 - The dead-time generator will reactivated if the timer clock is still provided, and drive the outputs according to the value of TIMx_CTRL2.OIx and TIMx_CTRL2.OIxN after the dead-time when (CCxP ^ OIx) ^ (CCxNP^OIxN)! = 0, that is, the OCx and OCxN still cannot be driven to active level at the same time. Note that the dead-time will be longer than usual because of the resynchronization on MOEN (almost 2 cycles of ck_tim).
 - Timer will release the output control if TIMx_BKDT.OSSI=0. Otherwise, if the enable output was high, it

137 / 319

will remain high. If it was low, it will become high when TIMx_CCEN.CCxEN or TIMx_CCEN.CCxNEN is high.

- If TIMx_DINTEN.BIEN=1, when TIMx_STS.BITF=1, an interrupt will be generated.
- If user set TIMx_BKDT.AOEN, the TIMx_BKDT.MOEN will be set automatically when the next UEV happened. User can use this to regulate. If user did not set TIMx_BKDT.AOEN, the TIMx_BKDT.MOEN will remain low until been set 1 again. At this situation, user can use this for security. User can connect the break input to thermal sensors, alarm for power drivers, or other security components.
- When the break input is active, TIMx_BKDT.MOEN cannot be set automatically or by software at the same time, and the TIMx_STS.BITF cannot be cleared. Because the break inputs are active on level.

To insure the security of application, the break circuit has the write protection function, and there is break input and output management too. It allow user to freeze some parameters, such as dead-time duration, OCx/OCxN polarities and state when disabled, OCxMD configurations, break enable and polarity. User can choose one of the 3 levels of protection to use by setting TIMx_BKDT.LCKCFG. However, the TIMx_BKDT.LCKCFG can only be written once after an MCU reset.

An example for output behavior in response to a break is as follow

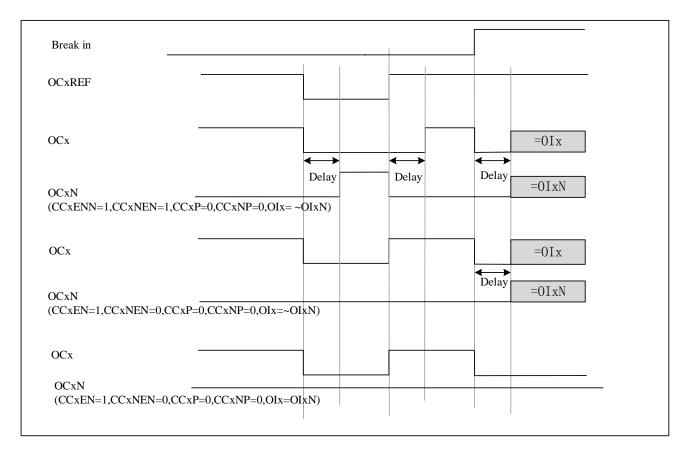

Figure 8-27 Output behavior in response to a break

8.3.15 Debug mode

When the microcontroller is in debug mode (the Cortex-M0 core halted), depending on the DBG_CTRL.TIMx_STOP

138 / 319

configuration in the PWR module, the TIMx counter can either continue to work normally or stop. For more details, see 3.4.9.

8.3.16 TIMx and external trigger synchronization

TIMx timers can be synchronized by a trigger in slave modes (reset, trigger and gated).

8.3.16.1 Slave mode: Reset mode

In reset mode, the trigger event can reset the counter and the prescaler updates the preload registers TIMx_AR, TIMx_CCDATx, and generates the update event UEV (TIMx_CTRL1.UPRS=0).

The following is an example of a reset mode:

1. Channel 1 is configured as input to detect the rising edge of TI1 (TIMx_CCMOD1.CC1SEL=01, TIMx_CCEN.CC1P=0);

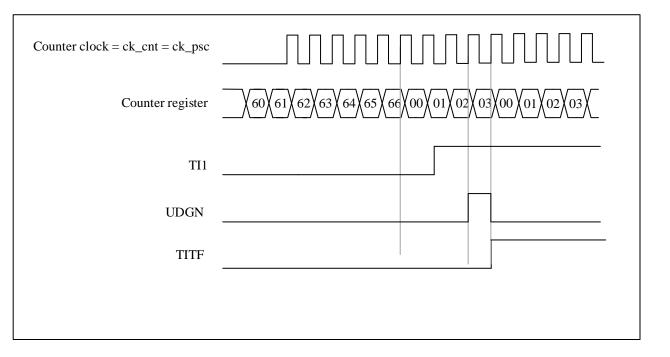

2. The slave mode is selected as reset mode (TIMx_SMCTRL.SMSEL=100), and the trigger input is selected as TI1 (TIMx_SMCTRL.TSEL=101);

3. Start counter(TIMx_CTRL1.CNTEN = 1).

After starting the timer, when TI1 detects a rising edge, the counter resets and restarts counting, and the trigger flag is set (TIMx_STS.TITF=1);

The delay between the rising edge on TI1 and the actual reset of the counter is due to the resynchronization circuit on TI1 input.

Figure 8-28 Control circuit in reset mode

8.3.16.2 Slave mode: Trigger mode

In trigger mode, the trigger event (rising edge/falling edge) of the input port can trigger the counter to start counting.

The following is an example of a trigger pattern:

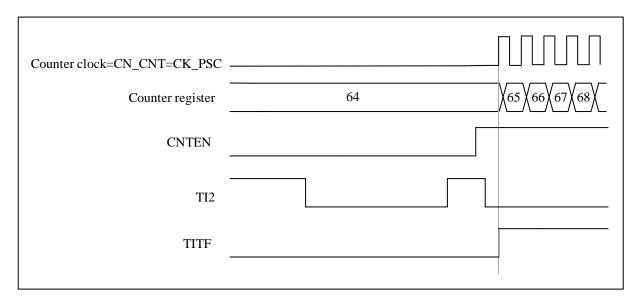

1. Channel 2 is configured as input to detect the rising edge of TI2 (TIMx_CCMOD1.CC2SEL=01, TIMx CCEN.CC2P=0);

2. Select from mode to trigger mode (TIMx_SMCTRL.SMSEL=110), select TI2 for trigger input (TIMx_SMCTRL.TSEL=110);

When TI2 detects a rising edge, the counter starts counting, and the trigger flag is set (TIMx_STS.TITF=1);

The delay between the rising edge on TI2 and the actual start of the counter is due to the resynchronization circuit on TI2 input.

Figure 8-29 Control circuit in Trigger mode

8.3.16.3 Slave mode: Gated mode

In gate control mode, the level polarity of the input port can control whether the counter counts.

The following is an example of a gated pattern:

1. Channel 1 is configured as input detection active low on TI1 (TIMx_CCMOD1.CC1SEL = 01, TIMx_CCEN.CC1P = 1);

2. Select the slave mode as the gated mode (TIMx_SMCTRL.SMSEL = 101), and select TI1 as the trigger input (TIMx_SMCTRL.TSEL = 101);

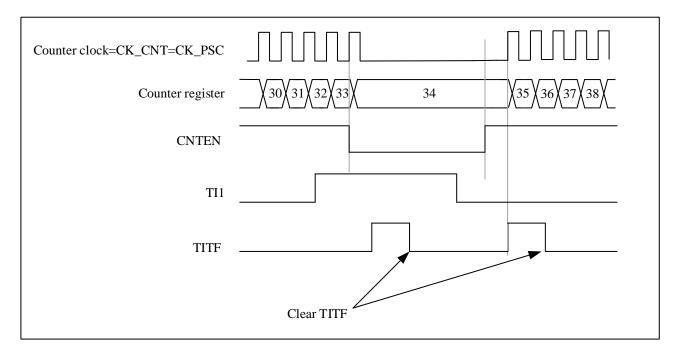

3. Start counter(TIMx_CTRL1.CNTEN = 1).

When TI1 detects that the level changes from low to high, the counter stops counting, and when TI1 detects that the level changes from high to low, the counter starts counting, and the trigger flag will be set when it starts or stops counting (TIMx_STS.TITF = 1);

The delay between the rising edge on TI1 and the actual stop of the counter is due to the resynchronization circuit on TI1 input.

Figure 8-30 Control circuit in Gated mode

8.3.16.4 Slave mode: Trigger Mode + External Clock Mode 2

In reset mode, trigger mode and gate control mode, the counter clock can be selected as external clock mode 2, and the ETR signal is used as the external clock source input. At this time, the trigger selection needs to select non-ETRF (TIMx_SMCTRL.TSEL=111).

Here is an example:

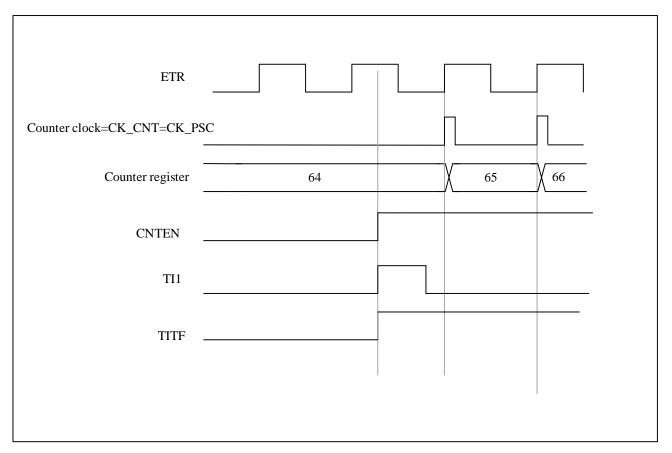

1. Channel 1 is configured as input to detect the rising edge of TI1 (TIMx_CCMOD1.CC1SEL=01, TIMx_CCEN.CC1P=0);

2. Enable external clock mode 2 (TIMx_SMCTRL.EXCEN=1), select rising edge for external trigger polarity (TIMx_SMCTRL.EXTP=0), select slave mode as trigger mode (TIMx_SMCTRL.SMSEL=110), select TI1 for trigger input (TIMx_SMCTRL.TSEL=101);

When TI1 detects a rising edge, the counter starts counting on the rising edge of ETR, and the trigger flag is set (TIMx_STS.TITF=1);

8.3.17 Timer synchronization

All TIM timers are internally connected for timer synchronization or chaining. For more details, see 9.3.14.

8.3.18 6-step PWM generation

In order to modify the configuration of all channels at the same time, the configuration of the next step can be set in advance (the preloaded bits are OCxMD, CCxEN and CCxNEN). When a COM commutation event occurs, the OCxMD, CCxEN, and CCxNEN preload bits are transferred to the shadow register bits.

COM commutation event generation method:

- 1. The software sets TIMx_EVTGEN.CCUDGN;
- 2. Generated by hardware on the rising edge of TRGI;

When a COM commutation event occurs, the TIMx_STS.COMITF flag will be set, enabling interrupts (TIMx_DINTEN.COMIEN) will generate interrupts.

The following figure shows the output timing diagram of OCx and OCxN when a COM commutation event occurs in three different configurations:

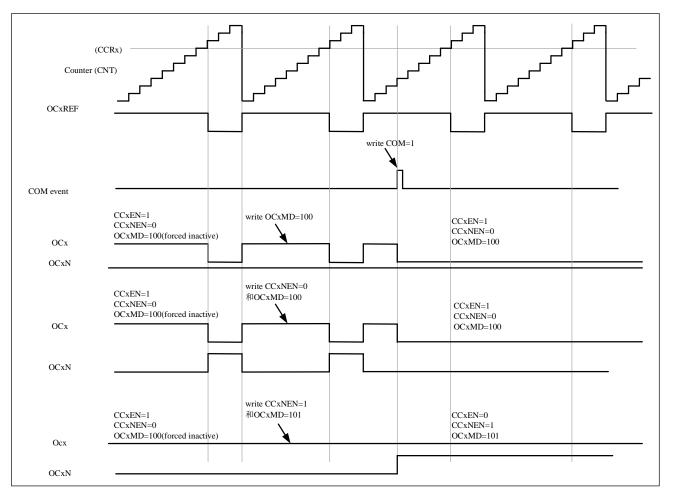

Figure 8-32 6-step PWM generation, COM example (OSSR=1)

		0: Select external CH1 signal from IOM
		1: Select internal CH1 signal from COMP
10	IOMBKPEN	Enabling IOM as BKP
		0: Enable
		1: Disable
9:8	CLKD[1:0]	Clock division
		CLKD[1:0] indicates the division ratio between CK_INT (timer clock) and DTS (clock used
		for dead-time generator and digital filters (ETR, TIx))
		00: $t_{DTS} = t_{CK_INT}$
		01: $t_{DTS} = 2 \times t_{CK_{INT}}$
		10: $t_{DTS} = 4 \times t_{CK_{INT}}$
		11: Reserved, do not use this configuration
7	ARPEN	ARPEN: Auto-reload preload enable
		0: Shadow register disable for TIMx_AR register
		1: Shadow register enable for TIMx_AR register
6:5	CAMSEL[1:0]	Center-aligned mode selection

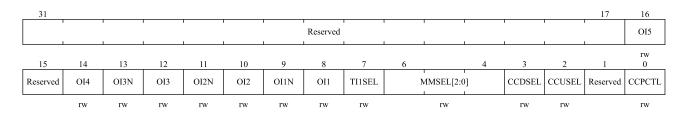

Bit field	Name	Description						
		00: Edge-aligned mode. TIMx_CTRL1.DIR specifies up-counting or down-counting.						
		01: Center-aligned mode 1. The counter counts in center-aligned mode, and the output						
		compare interrupt flag bit is set to 1 when down-counting.						
		10: Center-aligned mode 2. The counter counts in center-aligned mode, and the output						
		compare interrupt flag bit is set to 1 when up-counting.						
		11: Center-aligned mode 3. The counter counts in center-aligned mode, and the output						
		compare interrupt flag bit is set to 1 when up-counting or down-counting.						
		Note: Switching from edge-aligned mode to center-aligned mode is not allowed when the						
		counter is still enabled ($TIMx_CTRL1.CNTEN = 1$).						
1	DIR	Direction						
		0: Up-counting						
		1: Down-counting						
		Note: This bit is read-only when the counter is configured in center-aligned mode.						
3 C 2 U	ONEPM	One-pulse mode						
		0: Disable one-pulse mode, the counter counts are not affected when an update event occurs.						
		1: Enable one-pulse mode, the counter stops counting when the next update event occurs						
		(clearing TIMx_CTRL1.CNTEN bit)						
2	UPRS	Update request source						
		This bit is used to select the UEV event sources by software.						
		0: If update interrupt is enabled, any of the following events will generate an update interrupt :						
		 Counter overflow/underflow 						
		 The TIMx_EVTGEN.UDGN bit is set 						
		 Update generation from the slave mode controller 						
		1: If update interrupt is enabled, only counter overflow/underflow will generate update						
		interrupt						
1	UPDIS	Update disable						
		This bit is used to enable/disable the Update event (UEV) events generation by software.						
		0: Enable UEV. UEV will be generated if one of following condition been fulfilled:						
		 Counter overflow/underflow 						
		 The TIMx_EVTGEN.UDGN bit is set 						
		 Update generation from the slave mode controller 						
		Shadow registers will update with preload value.						
		1: UEV disabled. No update event is generated, and the shadow registers (AR, PSC, and						
		CCDATx) keep their values. If the TIMx_EVTGEN.UDGN bit is set or a hardware reset is						
		issued by the slave mode controller, the counter and prescaler are reinitialized.						
)	CNTEN	Counter Enable						
		0: Disable counter						
		1: Enable counter						
		<i>Note: external clock, gating mode can only work after TIMx_CTRL1.CNTEN bit is set in the</i>						
		software. Trigger mode can automatically set TIMx_CTRL1.CNTEN bit by hardware.						

8.4.3 Control register 2 (TIMx_CTRL2)

Offset address: 0x04

Reset value: 0x0000 0000

Bit field	Name	Description						
31:17	Reserved	Reserved, the reset value must be maintained						
16	OI5	Output idle state 5 (OC5 output). See TIMx_CTRL2.OI1 bit.						
15	Reserved	Reserved, the reset value must be maintained						
14	OI4	Output idle state 4 (OC4 output). See TIMx_CTRL2.OI1 bit.						
13	OI3N	Output idle state 3 (OC3N output). See TIMx_CTRL2.OI1N bits.						
12	OI3	Output idle state 3 (OC3 output). See TIMx_CTRL2.OI1 bit.						
11	OI2N	Output idle state 2 (OC2N output). See TIMx_CTRL2.OI1N bits.						
10	OI2	Output idle state 2 (OC2 output). See TIMx_CTRL2.OI1 bit.						
9	OI1N	Output Idle state 1 (OC1N Output)						
		0: When TIMx_BKDT.MOEN = 0, after dead-time $OC1N = 0$						
		1: When $TIMx_BKDT.MOEN = 0$, after dead-time $OC1N = 1$						
8	OI1	Output Idle state 1						
		0: When TIMx_BKDT.MOEN = 0, if OC1N is implemented, after dead-time $OC1 = 0$						
		1: When TIMx_BKDT.MOEN = 0, if OC1N is implemented, after dead-time $OC1 = 1$						
7	TI1SEL	TI1 selection						
		0: TIMx_CH1 pin connected to TI1 input.						
		1: TIMx_CH1, TIMx_CH2, and TIMx_CH3 pins are XOR connected to the TI1 input.						
6:4	MMSEL[2:0]	Master Mode Selection						
		These 3 bits (TIMx_CTRL2. MMSEL [2:0]) are used to select the synchronization information						
		(TRGO) sent to the slave timer in the master mode. Possible combinations are as follows:						
		000: Reset –When the TIMx_EVTGEN.UDGN is set or a reset is generated by the slave mode						
		controller, a TRGO pulse occurs. And in the latter case, the signal on TRGO is delayed						
		compared to the actual reset.						
		001: Enable - The TIMx_CTRL1.CNTEN bit is used as the trigger output (TRGO). Sometimes						
		you need to start multiple timers at the same time or enable slave timer for a period of time.						
		The counter enable signal is set when TIMx_CTRL1.CNTEN bit is set or the trigger input in						
		gated mode is high.						
		When the counter enable signal is controlled by the trigger input, there is a delay on TRGO						
		except if the master/slave mode is selected (see the description of the TIMx_SMCTRL.MSMD						
		bit).						

Bit field	Name	Description						
		010: Update - The update event is selected as the trigger output (TRGO). For example, a master						
		timer clock can be used as a slave timer prescaler.						
		011: Compare pulse - Triggers the output to send a positive pulse (TRGO) when the						
		TIMx_STS.CC1ITF is to be set (even if it is already high), when a capture or a comparison						
		succeeds.						
		100: Compare - OC1REF signal is used as the trigger output (TRGO).						
		101: Compare - OC2REF signal is used as the trigger output (TRGO).						
		110: Compare - OC3REF signal is used as the trigger output (TRGO).						
		111: Compare - OC4REF signal is used as the trigger output (TRGO).						
3	Reserved	Reserved, the reset value must be maintained						
2	CCUSEL	Capture/compare control update selection						
		0: If TIMx_CTRL2.CCPCTL = 1, they can only be updated by setting CCUDGN bits						
		1: If TIMx_CTRL2.CCPCTL = 1, they can be updated by setting CCUDGN bits or a rising edge						
		on TRGI.						
		Note: This bit only applied to channels with complementary outputs.						
1	Reserved	Reserved, the reset value must be maintained						
0	CCPCTL	Capture/ Compare preloaded control						
		0: No preloading of CCxEN, CCxNEN and OCxMD bits occurs.						
		1: Preloading of CCxEN, CCxNEN and OCxMD bits occurs. they are updated only when a						
		commutation event COM occurs (TIMx_EVTGEN.CCUDGN bit set or rising edge on TRGI						
		depending on CCUSEL bit)						
		Note: This bit only applied to channels with complementary outputs.						

8.4.4 Slave mode control register (TIMx_SMCTRL)

Offset address: 0x08

Reset value: 0x0000

15	14	13 12	11		8	7	6	4	3	2	0
EXTP	EXCEN	EXTPS[1:0]		EXTF[3:0]	1	MSMD	TS	EL[2:0]	Reserved	5	SMSEL[2:0]
rw	rw	rw		rw		rw		rw			rw

Bit field	Name	Description
15	EXTP	External trigger polarity
		This bit is used to select whether the trigger operation is to use ETR or the inversion of ETR.
		0: ETR active at high level or rising edge.
		1: ETR active at low level or falling edge.
14	EXCEN	External clock enable
		This bit is used to enable external clock mode 2, and the counter is driven by any active edge on
		the ETRF signal in this mode.
		0: External clock mode 2 disable.
		1: External clock mode 2 enable.

Bit field	Name	Description
		Note 1: When external clock mode 1 and external clock mode 2 are enabled at the same time, the
		input of the external clock is ETRF.
		Note 2: The following slave modes can be used simultaneously with external clock mode 2: reset
		mode, gated mode and trigger mode; However, TRGI cannot connect to ETRF
		$(TIMx_SMCTRL.TSEL \neq '111').$
		Note 3: Setting the TIMx_SMCTRL.EXCEN bit has the same effect as selecting external clock
		mode 1 and connecting TRGI to ETRF (TIMx_SMCTRL.SMSEL = 111 and TIMx_SMCTRL.TSEL
		= 111).
13:12	EXTPS[1:0]	External trigger prescaler
		The frequency of the external trigger signal ETRP must be at most 1/4 of TIMxCLK frequency.
		When a faster external clock is input, a prescaler can be used to reduce the frequency of ETRP.
		00: Prescaler disable
		01: ETRP frequency divided by 2
		10: ETRP frequency divided by 4
		11: ETRP frequency divided by 8
11:8	EXTF[3:0]	External trigger filter
		These bits are used to define the frequency at which the ETRP signal is sampled and the
		bandwidth of the ETRP digital filtering. In effect, the digital filter is an event counter that
		generates a validate output after consecutive N events are recorded.
		0000: No filter, sampling at f _{DTS}
		0001: $f_{SAMPLING} = f_{CK_INT}$, N = 2
		0010: $f_{SAMPLING} = f_{CK_INT}$, N = 4
		0011: $f_{SAMPLING} = f_{CK_INT}, N = 8$
		0100: $f_{SAMPLING} = f_{DTS}/2$, N = 6
		0101: $f_{SAMPLING} = f_{DTS}/2$, N = 8
		0110: $f_{SAMPLING} = f_{DTS}/4$, N = 6
		0111: $f_{SAMPLING} = f_{DTS}/4$, N = 8
		1000: $f_{SAMPLING} = f_{DTS}/8$, N = 6
		1001: $f_{SAMPLING} = f_{DTS}/8$, N = 8
		1010: $f_{SAMPLING} = f_{DTS}/16$, N = 5
		$1011: f_{SAMPLING} = f_{DTS}/16, N = 6$
		1100: $f_{SAMPLING} = f_{DTS}/16$, N = 8
		1101: $f_{SAMPLING} = f_{DTS}/32, N = 5$
		1110: $f_{SAMPLING} = f_{DTS}/32$, N = 6
		1111: $f_{SAMPLING} = f_{DTS}/32, N = 8$
7	MSMD	Master/ Slave mode
		0: No action
		1: Events on the trigger input (TRGI) are delayed to allow a perfect synchronization between the
		current timer (via TRGO) and its slaves. This is useful when several timers are required to be
		synchronized to a single external event.

Bit field	Name	Description						
6:4	TSEL[2:0]	Trigger selection						
		These 3 bits are used to select the trigger input of the synchronous counter.						
		000: Internal trigger 0 (ITR0) 100: TI1 edge detector (TI1F_ED)						
		001: Internal trigger 1 (ITR1) 101: Filtered timer input 1 (TI1FP1)						
		010: Internal trigger 2 (ITR2) 110: Filtered timer input 2 (TI2FP2)						
		011: Internal trigger 3 (ITR3) 111: External triggered Input (ETRF)						
		For more details on ITRx, see Table 8-2 below.						
		Note: These bits must be changed only when not in use (e. g. TIMx_SMCTRL.SMSEL=000) to						
		avoid false edge detection at the transition.						
3	Reserved	Reserved, the reset value must be maintained						
2:0	SMSEL[2:0]	Slave mode selection						
		When an external signal is selected, the active edge of the trigger signal (TRGI) is linked to the						
		selected external input polarity (see input control register and control register description)						
		000: Disable slave mode. If TIMx_CTRL1.CNTEN = 1, the prescaler is driven directly by the						
		internal clock.						
		001: reserved.						
		010: reserved.						
		011: reserved.						
		100: Reset mode. On the rising edge of the selected trigger input (TRGI), the counter is						
		reinitialized and the shadow register is updated.						
		101: Gated mode. When the trigger input (TRGI) is high, the clock of the counter is enabled. Once						
		the trigger input becomes low, the counter stops counting, but is not reset. In this mode, the start						
		and stop of the counter are controlled.						
		110: Trigger mode. When a rising edge occurs on the trigger input (TRGI), the counter is started						
		but not reset. In this mode, only the start of the counter is controlled.						
		111: External clock mode 1. The counter is clocked by the rising edge of the selected trigger input						
		(TRGI).						
		Note: Do not use gated mode if TIIF_ED is selected as the trigger input						
		(TIMx_SMCTRL.TSEL=100). This is because TI1F_ED outputs a pulse for each TI1F transition,						
		whereas gated mode checks the level of the triggered input.

	Name	Description
31: 17	Reserved	Reserved, the reset value must be maintained
16	CC5ITF	Capture/Compare 5 interrupt flag
		See TIMx_STS.CC1ITF description.
15: 13	Reserved	Reserved, the reset value must be maintained
12	CC40CF	Capture/Compare 4 overcapture flag
		See TIMx_STS.CC1OCF description.
11	CC3OCF	Capture/Compare 3 overcapture flag
		See TIMx_STS.CC1OCF description.
10	CC2OCF	Capture/Compare 2 overcapture flags
		See TIMx_STS.CC1OCF description.
9	CC10CF	Capture/Compare 1 overcapture flag
		This bit is set by hardware only when the corresponding channel is configured in input capture
		mode. Cleared by software writing 0.
		0: No overcapture occurred
		1: TIMx_STS.CC1ITF was already set when the value of the counter has been captured in the
		TIMx_CCDAT1 register.
8	Reserved	Reserved, the reset value must be maintained
7	BITF	Break interrupt flag
		This bit is set by hardware once the brake input is active. This bit is cleared by software when
		the brake input becomes inactive.
		0: No break event occurred
		1: An active level has been detected
6	TITF	Trigger interrupt flag
		This bit is set by hardware when an active edge is detected on the TRGI input when the slave
		mode controller is in a mode other than gated. This bit is set by hardware when any edge in
		gated mode is detected. This bit is cleared by software.
		0: No trigger event occurred
		1: Trigger interrupt occurred
5	COMITF	COM interrupt flag
		This bit is set by hardware once a COM event is generated (when TIMx_CCEN.CCxEN,
		TIMx_CCEN.CCxNEN, TIMx_CCMOD1.OCxMD have been updated). This bit is cleared by
		software.
		0: No COM event occurred
		1: COM interrupt pending
4	CC4ITF	Capture/Compare 4 interrupt flag
		See TIMx_STS.CC1ITF description.
3	CC3ITF	Capture/Compare 3 interrupt flag
		See TIMx_STS.CC1ITF description.
2	CC2ITF	Capture/Compare 2 interrupt flag
		See TIMx_STS.CC1ITF description.
1	CC1ITF	Capture/Compare 1 interrupt flag
		When the corresponding channel of CC1 is in output mode:

152/319

Bit field	Name	Description
		Except in center-aligned mode, this bit is set by hardware when the counter value is the same as
		the compare value (see TIMx_CTRL1.CAMSEL bit description). This bit is cleared by
		software.
		0: No match occurred.
		1: The value of TIMx_CNT is the same as the value of TIMx_CCDAT1.
		When the value of TIMx_CCDAT1 is greater than the value of TIMx_AR, the
		TIMx_STS.CC1ITF bit will go high if the counter overflows (in up-counting and up/down-
		counting modes) and underflows in down-counting mode.
		When the corresponding channel of CC1 is in input mode:
		This bit is set by hardware when the capture event occurs. This bit is cleared by software or by
		reading TIMx_CCDAT1.
		0: No input capture occurred.
		1: Input capture occurred. Counter value has captured in the TIMx_CCDAT1. An edge with the
		same polarity as selected has been detected on IC1.
0	UDITF	Update interrupt flag
		This bit is set by hardware when an update event occurs under the following conditions:
		- When TIMx_CTRL1.UPDIS = 0, and repeat counter value overflow or underflow (An
		update event is generated when the repeat counter equals 0).
		- When TIMx_CTRL1.UPRS = 0, TIMx_CTRL1.UPDIS = 0, and set the
		TIMx_EVTGEN.UDGN bit by software to reinitialize the CNT.
		- When TIMx_CTRL1.UPRS = 0, TIMx_CTRL1.UPDIS = 0, and the counter CNT is
		reinitialized by the trigger event. (See TIMx_SMCTRL Register description)
		This bit is cleared by software.
		0: No update event occurred
		1: Update interrupt occurred

8.4.7 Event generation registers (TIMx_EVTGEN)

Offset address: 0x14

Reset values: 0x0000

15					8	7	6	5	4	3	2	1	0
	1	Rese	erved	1		BGN	TGN	CCUDGN	CC4GN	CC3GN	CC2GN	CC1GN	UDGN
	•		•		•	w	w	w	w	w	w	w	w

Bit field	Name	Description
15: 8	Reserved	Reserved, the reset value must be maintained
7	BGN	Break generation
		This bit can generate a brake event when set by software. And at this time TIMx_BKDT.MOEN
		= 0, TIMx_STS.BITF = 1, if the corresponding interrupt is enabled, the corresponding interrupt
		will be generated. This bit is automatically cleared by hardware.
		0: No action
		1: Generated a break event

Bit field	Name	Description
6	TGN	Trigger generation
		This bit can generate a trigger event when set by software. And at this time TIMx_STS.TITF =
		1, if the corresponding interrupt is enabled, the corresponding interrupt will be generated. This
		bit is automatically cleared by hardware.
		0: No action
		1: Generated a trigger event
5	CCUDGN	Capture/Compare control update generation
		This bit is set by software. And if TIMx_CTRL2.CCPCTL = 1 at this time, the CCxEN,
		CCxNEN and OCxMD bits are allowed to be updated. This bit is automatically cleared by
		hardware.
		0: No action
		1: Generated a COM event
		Note: This bit is only valid for channels with complementary outputs.
4	CC4GN	Capture/Compare 4 generation
		See TIMx_EVTGEN.CC1GN description.
3	CC3GN	Capture/Compare 3 generation
		See TIMx_EVTGEN.CC1GN description.
2	CC2GN	Capture/Compare 2 generation
		See TIMx_EVTGEN.CC1GN description.
1	CC1GN	Capture/Compare 1 generation
		This bit can generate a capture/compare event when set by software. This bit is automatically
		cleared by hardware.
		When the corresponding channel of CC1 is in output mode:
		The TIMx_STS.CC1ITF flag will be pulled high, if the corresponding interrupt and is enabled,
		the corresponding interrupt will be generated.
		When the corresponding channel of CC1 is in input mode:
		TIMx_CCDAT1 will capture the current counter value, and the TIMx_STS.CC1ITF flag will be
		pulled high, if the corresponding interrupt is enabled, the corresponding interrupt will be
		generated. If The TIMx_STS.CC1ITF is already pulled high, pull TIMx_STS.CC1OCF high.
		0: No action
		1: Generated a CC1 capture/compare event
0	UDGN	Update generation
		This bit can generate an update event when set by software. And at this time the counter will be
		reinitialized, the prescaler counter will be cleared, the counter will be cleared in center-aligned or up-
		counting mode, but take TIMx_AR in down-counting mode the value of the register. This bit is
		automatically cleared by hardware.
		0: No action
		1: Generated an update event

8.4.8 Capture/compare mode register 1 (TIMx_CCMOD1)

Offset address: 0x18

Reset value: 0x0000

Channels can be used for input (capture mode) or output (compare mode), and the direction of the channel is defined by the corresponding CCxSEL bit. The other bits of the register act differently in input and output modes. OCx describes the function of a channel in output mode, ICx describes the function of a channel in input mode. Hence, please note that the same bit can have different meanings for output mode and for input mode.

Output compare mode:

15	14		12	11	10	9	8	7	6		4	3	2	1	0
OC2CEN		OC2M[2:0]]	OC2PEN	OC2FEN	CC2SI	EL[1:0]	OC1CEN		OC1M[2:0]		OC1PEN	OC1FEN	CC1SE	EL[1:0]
rw		rw		rw	rw	r	W	rw		rw		rw	rw	r	W

Bit field	Name	Description
15	OC2CEN	Output Compare 2 clear enable
14:12	OC2MD[2:0]	Output Compare 2 mode
11	OC2PEN	Output Compare 2 preload enable
10	OC2FEN	Output Compare 2 fast enable
9:8	CC2SEL[1:0]	Capture/compare 2 selection
		These bits are used to select the input/output and input mapping of the channel
		00: CC2 channel is configured as output
		01: CC2 channel is configured as input, IC2 is mapped on TI2
		10: CC2 channel is configured as input, IC2 is mapped on TI1
		11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode is only active
		when the internal trigger input is selected by TIMx_SMCTRL.TSEL.
		<i>Note:</i> CC2SEL is writable only when the channel is off ($TIMx_CCEN.CC2EN = 0$).
7	OC1CEN	Output Compare 1 clear enable
		0: OC1REF is not affected by ETRF input level
		1: OC1REF is cleared immediately when the ETRF input level is detected as high
6:4	OC1MD[2:0]	Output Compare 1 mode
		These bits are used to manage the output reference signal OC1REF, which determines the
		values of OC1 and OC1N, and is valid at high levels, while the active levels of OC1 and
		OC1N depend on the TIMx_CCEN.CC1P and TIMx_CCEN.CC1NP bits.
		000: Frozen. Comparison between TIMx_CCDAT1 register and counter TIMx_CNT has no
		effect on OC1REF signal.
		001: Set channel 1 to the active level on match. When TIMx_CCDAT1 = TIMx_CNT,
		OC1REF signal will be forced high.
		010: Set channel 1 as inactive level on match. When TIMx_CCDAT1 = TIMx_CNT,
		OC1REF signal will be forced low.
		011: Toggle. When TIMx_CCDAT1 = TIMx_CNT, OC1REF signal will be toggled.
		100: Force to inactive level. OC1REF signal is forced low.
		101: Force to active level. OC1REF signal is forced high.
		110: PWM mode 1 - In up-counting mode, if TIMx_CNT < TIMx_CCDAT1, OC1REF signal
		of channel 1 is high, otherwise it is low. In down-counting mode, if TIMx_CNT >
		TIMx_CCDAT1, OC1REF signal of channel 1 is low, otherwise it is high.

Bit field	Name	Description
		111: PWM mode 2 - In up-counting mode, if TIMx_CNT < TIMx_CCDAT1, OC1REF signal
		of channel 1 is low, otherwise it is high. In down-counting mode, if TIMx_CNT >
		TIMx_CCDAT1, OC1REF signal of channel 1 is high, otherwise it is low.
		Note 1: In PWM mode 1 or PWM mode 2, the OC1REF level changes only when the
		comparison result changes or when the output compare mode is switched from frozen mode to
		PWM mode.
3	OC1PEN	Output Compare 1 preload enable
		0: Disable preload function of TIMx_CCDAT1 register. Supports write operations to
		TIMx_CCDAT1 register at any time, and the written value is effective immediately.
		1: Enable preload function of TIMx_CCDAT1 register. Only read and write operations to
		preload registers. When an update event occurs, the value of TIMx_CCDAT1 is loaded into
		the active register.
		Note 1: Only when TIMx_CTRL1.ONEPM = 1(In one-pulse mode), PWM mode can be used
		without verifying the preload register, otherwise no other behavior can be predicted.
2	OC1FEN	Output Compare 1 fast enable
		This bit is used to speed up the response of the CC output to the trigger input event.
		0: CC1 behaves normally depending on the counter and CCDAT1 values, even if the trigger is
		ON. The minimum delay for activating CC1 output when an edge occurs on the trigger input
		is 5 clock cycles.
		1: An active edge of the trigger input acts like a comparison match on CC1 output. Therefore,
		OC is set to the comparison level regardless of the comparison result. The delay time for
		sampling the trigger input and activating the CC1 output is reduced to 3 clock cycles.
		OCxFEN only works if the channel is configured in PWM1 or PWM2 mode.
1:0	CC1SEL[1:0]	Capture/compare 1 selection
		These bits are used to select the input/output and input mapping of the channel
		00: CC1 channel is configured as output
		01: CC1 channel is configured as input, IC1 is mapped on TI1
		10: CC1 channel is configured as input, IC1 is mapped on TI2
		11: CC1 channels are configured as inputs and IC1 is mapped to TRC. This mode is only
		active when the internal trigger input is selected by TIMx_SMCTRL.TSEL.
		Note: CC1SEL is writable only when the channel is off ($TIMx_CCEN.CC1EN = 0$).

Input capture mode:

15		12	11	10	9	8	7		4	3	2	1	0

	rw			rw rw				rw	r	w	r	w	
Bit field	Name		Descr	Description									
15.12	IC2E[2,0]	Insuit Contume 2 Filter											

15:12	IC2F[3:0]	Input Capture 2 Filter
11:10	IC2PSC[1:0]	Input Capture 2 Prescaler

Name	Description
CC2SEL[1:0]	Capture/Compare 2 selection
	These bits are used to select the input/output and input mapping of the channel
	00: CC2 channel is configured as output
	01: CC2 channel is configured as input, IC2 is mapped on TI2
	10: CC2 channel is configured as input, IC2 is mapped on TI1
	11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode is only active when
	the internal trigger input is selected by TIMx_SMCTRL.TSEL.
	Note: CC2SEL is writable only when the channel is off ($TIMx_CCEN.CC2EN = 0$).
IC1F[3:0]	Input Capture 1 filter
	These bits are used to define sampling frequency of TI1 input and the length of digital filter. The
	digital filter is an event counter that generates an output transition after N events are recorded.
	0000: No filter, sampling at fors frequency
	0001 : fsampling = fck_int, N = 2
	0010: $f_{\text{SAMPLING}} = f_{\text{CK_INT}}$, N = 4
	$0011: f_{SAMPLING} = f_{CK_{INT}}, N = 8$
	0100: $f_{SAMPLING} = f_{DTS}/2$, N = 6
	0101: $f_{SAMPLING} = f_{DTS}/2$, N = 8
	0110: $f_{SAMPLING} = f_{DTS}/4$, N = 6
	0111: $f_{SAMPLING} = f_{DTS}/4$, N = 8
	1000: $f_{\text{SAMPLING}} = f_{\text{DTS}}/8$, N = 6
	1001: $f_{\text{SAMPLING}} = f_{\text{DTS}}/8$, N = 8
	1010: $f_{SAMPLING} = f_{DTS}/16$, N = 5
	1011: $f_{SAMPLING} = f_{DTS}/16$, N = 6
	1100: $f_{SAMPLING} = f_{DTS}/16$, N = 8
	1101: $f_{SAMPLING} = f_{DTS}/32$, N = 5
	1110: $f_{SAMPLING} = f_{DTS}/32$, N = 6
	1111: $f_{SAMPLING} = f_{DTS}/32$, N = 8
IC1PSC[1:0]	Input Capture 1 prescaler
[]	These bits are used to select the ratio of the prescaler for IC1 (CC1 input).
	When TIMx_CCEN.CC1EN = 0, the prescaler will be reset.
	00: No prescaler, capture is done each time an edge is detected on the capture input
	01: Capture is done once every 2 events
	10: Capture is done once every 4 events
	11: Capture is done once every 8 events
CC1SFL[1:0]	Capture/Compare 1 selection
CCIDEL[1.0]	These bits are used to select the input/output and input mapping of the channel
	00: CC1 channel is configured as output
	01: CC1 channel is configured as input, IC1 is mapped on TI1
	10: CC1 channel is configured as input, IC1 is mapped on TI2
	11: CC1 channel is configured as input, IC1 is mapped to TRC. This mode is only active when the internal triager input is selected by TIMx_SMCTPL_TSEL
	the internal trigger input is selected by TIMx_SMCTRL.TSEL.
_	CC2SEL[1:0]

157 / 319

8.4.9 Capture/compare mode register 2 (TIMx_CCMOD2)

Offset address: 0x1C

Reset value: 0x0000

See the description of the CCMOD1 register above

Output comparison mode:

15	14		12	11	10	9	8	7	6		4	3	2	1	0

		See TIMx_CCEN.CC1NEN description.
5	CC2P	Capture/Compare 2 output polarity
		See TIMx_CCEN.CC1P description.
4	CC2EN	Capture/Compare 2 output enable
		See TIMx_CCEN.CC1EN description.
3	CC1NP	Capture/Compare 1 complementary output polarity
		0: OC1N active high
		1: OC1N active low
2	CC1NEN	Capture/Compare 1 complementary output enable
		0: Disable - Disable output OC1N signal. The level of OC1N depends on the value of these bits
		TIMx_BKDT.MOEN, TIMx_BKDT.OSSI, TIMx_BKDT.OSSR, TIMx_CTRL2.OI1,
		TIMx_CTRL2.0I1N and TIMx_CCEN.CC1EN.
		1: Enable - Enable output OC1N signal. The level of OC1N depends on the value of these bits
		TIMx_BKDT.MOEN, TIMx_BKDT.OSSI, TIMx_BKDT.OSSR, TIMx_CTRL2.OI1,
		TIMx_CTRL2.0I1N and TIMx_CCEN.CC1EN.
1	CC1P	Capture/Compare 1 output polarity
		When the corresponding channel of CC1 is in output mode:
		0: OC1 active high
		1: OC1 active low
		When the corresponding channel of CC1 is in input mode:
		At this time, this bit is used to select whether IC1 or the inverse signal of IC1 is used as the trigger
		or capture signal.
		0: non-inverted: Capture action occurs when IC1 generates a rising edge. When used as external
		trigger, IC1 is non-inverted.
		1: inverted: Capture action occurs when IC1 generates a falling edge. When used as external
		trigger, IC1 is inverted.
		Note: If $TIMx_BKDT.LCKCFG = 3$ or 2, these bits cannot be modified.

160 / 319

Bit field	Name	Description
0	CC1EN	Capture/Compare 1 output enable
		When the corresponding channel of CC1 is in output mode:
		0: Disable - Disable output OC1 signal. The level of OC1 depends on the value of these bits
		TIMx_BKDT.MOEN, TIMx_BKDT.OSSI, TIMx_BKDT.OSSR, TIMx_CTRL2.0I1,
		TIMx_CTRL2.011N and TIMx_CCEN.CC1NEN.
		1: Enable - Enable output OC1 signal. The level of OC1N depends on the value of these bits
		TIMx_BKDT.MOEN, TIMx_BKDT.OSSI, TIMx_BKDT.OSSR, TIMx_CTRL2.011,
		TIMx_CTRL2.011N and TIMx_CCEN.CC1NEN.
		When the corresponding channel of CC1 is in input mode:
		At this time, this bit is used to disable/enable the capture function.
		0: Disable capture
		1: Enable capture

Table 8-3 Output control bits of complementary OCx and OCxN channels with break function

Control	bits				Output state ¹⁾

0	0	Х	0	0	Output disabled (not driven by timer)						
	0		0	1	Asynchronously: OCx=CCxP, OCx_B	EN=0, OCxN=CCxNP,OCxN_EN=0;					

Control	bits				Output state ¹⁾							
MOEN	OSSI	OSSR	CCxEN	CCxNEN	OCx Output state OCxN Output state							
	0		1	0	Then if the clock is present: OCx=OIx and OCxN=OIxN after a dead-time, when							
	0		1	1	$(CCxP \land OIx) \land (CCxNP \land OIxN)! = 0.$							
	1		0	0	Off-state (Output enabled with inactive s	state)						
	1		0	1	Asynchronously: OCx=CCxP, OCx_E	N=1, OCxN=CCxNP,OCxN_EN=1;						
	1		1	0	Then if the clock is present: OCx=OIx and OCxN=OIxN after a dead-time, when							
	1		1	1	$(CCxP \land OIx) \land (CCxNP \land OIxN)! = 0.$							

1. If both outputs of a channel are not used (CCxEN = CCxNEN = 0), OIx, OIxN, CCxP and CCxNP must all be cleared.

Note: The status of external I/O pins connected to complementary OCx and OCxN channels depends on the OCx and OCxN channel states and GPIO and AFIO registers.

8.4.11 Counters (TIMx_CNT)

Bit field	Name	Description
15:8	Reserved	Reserved, the reset value must be maintained
7:0	REPCNT[7:0]	Repetition counter value
		Repetition counter is used to generate the update event or update the timer registers only after a
		given number $(N+1)$ cycles of the counter, where N is the value of TIMx_REPCNT.REPCNT .
		The repetition counter is decremented at each counter overflow in up-counting mode, at each
		counter underflow in down-counting mode or at each counter overflow and at each counter
		underflow in center-aligned mode. Setting the TIMx_EVTGEN.UDGN bit will reload the content
		of TIMx_REPCNT.REPCNT and generate an update event.

		CC4 channel is configured as input:
		CCDAT4 contains the counter value transferred by the last input capture 4 event (IC4).
		When configured as input mode, register CCDAT4 and CCDDAT4 are only readable.
		When configured as output mode, register CCDAT4 and CCDDAT4 are readable and writable.

8.4.19 Break and Dead-time registers (TIMx_BKDT)

Offset address: 0x44

Reset value: 0x0000

Note: AOEN, BKP, BKEN, OSSI, OSSR, and DTGN [7:0] bits can all be write protected depending on the LOCK

165 / 319

Nations Technologies Inc. Tel: +86-755-86309900 Email: info@nationstech.com Address: Nations Tower, #109 Baoshen Road, Hi-tech Park North. Nanshan District, Shenzhen, 518057, P.R.China

configuration, and it is necessary to configure all of them on the first write to the TIMx_BKDT register.

Bit field	Name	Description					
15 MOEN		Main Output enable					
		This bit can be set by software or hardware depending on the TIMx_BKDT.AOEN bit, and is					
		asynchronously cleared to '0' by hardware once the brake input is active. It is only valid for					
		channels configured as outputs.					
		0: OC and OCN outputs are disabled or forced to idle state.					
		1: OC and OCN outputs are enabled if TIMx_CCEN.CCxEN or TIMx_CCEN.CCxNEN bits are					
		set. For more details, see Section 8.4.10 Capture/Compare enable registers (TIMx_CCEN).					
14	AOEN	Automatic output enable					
		0: Only software can set TIMx_BKDT.MOEN;					
		1: Software sets TIMx_BKDT.MOEN; or if the break input is not active, when the next update					
		event occurs, hardware automatically sets TIMx_BKDT.MOEN.					
13	ВКР	Break input polarity					
		0: Low level of the brake input is valid					
		1: High level of the brake input is valid					
		Note: Any write to this bit requires an APB clock delay to take effect.					
12	BKEN	Break enable					
		0: Disable brake input (BRK and CCS clock failure events)					
		1: Enable brake input (BRK and CCS clock failure events)					
		Note: Any write to this bit requires an APB clock delay to take effect.					
11	OSSR	Off-state Selection for Run Mode					
		This bit is used when TIMx_BKDT.MOEN=1 and the channel is a complementary output.					
		The OSSR bit does not exist in timer without complementary outputs.					
		0: When inactive, $OCx/OCxN$ outputs are disabled ($OCx/OCxN$ enable output signal = 0)					
		1: When inactive, OCx/OCxN outputs are enabled with their inactive level as soon as CCxEN = 1					
		or $CCxNEN = 1$. Then, $OCx/OCxN$ enable output signal = 1					
		For more details, See Section 8.4.10, capture/compare enablement registers (TIMx_CCEN).					
10	OSSI	Off-state Selection for Idle Mode					
		This bit is used when TIMx_BKDT.MOEN=0 and the channels configured as outputs.					
		0: When inactive, $OCx/OCxN$ outputs are disabled ($OCx/OCxN$ enable output signal = 0)					
		1: When inactive, $OCx/OCxN$ outputs are enabled with their idle level as soon as $CCxEN = 1$ or					
		CCxNEN = 1. Then, $OCx/OCxN$ enable output signal = 1					
		For more details, See Section 8.4.10, capture/compare enablement registers (TIMx_CCEN).					
9:8	LCKCFG[1:0]	Lock Configuration					
		These bits offer a write protection against software errors.					
		00:					
		– No write protected.					
		01:					
		– LOCK Level 1					
		TIMx_BKDT.DTGN, TIMx_BKDT.BKEN, TIMx_BKDT.BKP, TIMx_BKDT.AOEN,					

Bit field	Name	Description
		TIMx_CTRL2.OIx, TIMx_CTRL2.OIxN bits enable write protection.
		10:
		– LOCK Level 2
		Except for register write protection in LOCK Level 1 mode, TIMx_CCEN.CCxP and
		TIMx_CCEN.CCxNP (If the corresponding channel is configured in output mode),
		TIMx_BKDT.OSSR and TIMx_BKDT.OSSI bits also enable write protection.
		11:
		– LOCK Level 3
		Except for register write protection in LOCK Level 2, TIMx_CCMODx.OCxMD and
		TIMx_CCMODx.OCxPEN bits (If the corresponding channel is configured in output mode) also
		enable write protection.
		Note: After the system reset, the LCKCFG bit can only be written once. Once written to the
		TIMx_BKDT register, LCKCFG will be protected until the next reset.
7:0	DTGN [7:0]	Dead-time Generator
		These bits define the dead-time duration between inserted complementary outputs. The
		relationship between the DTGN value and the dead time is as follows::
		DTGN[7:5] = 0xx:
		dead time = DTGN[7:0] \times (t _{DTS})
		DTGN[7:5] = 10x:
		dead time =(64+DTGN[5:0]) \times (2 \times t _{DTS})
		DTGN[7:5]=110:
		dead time = $(32+DTGN[4:0]) \times (8 \times t_{DTS})$
		DTGN [then] = 111:
		dead time = $(32 + \text{DTGN } [4:0]) \times (16 \times t_{\text{DTS}})$
		t _{DTS} value see TIMx_CTRL1.CLKD [1:0].

Bit field	Name	Description
15:0	CCDAT5[15:0]	Capture/Compare 5 value
		CC5 channel can only configured as output:
		CCDAT5 contains the value to be compared to the counter TIMx_CNT, signaling on the OC5
		output.
		If the preload feature is not selected in TIMx_CCMOD3.OC5PEN bit, the written value is
		immediately transferred to the active register. Otherwise, this preloaded value is transferred to
		the active register only when an update event occurs.
		TIM1_CC5 and TIM8_CC5 is used for comparator blanking.

9 General-purpose timers (TIM3)

9.1 General-purpose timers introduction

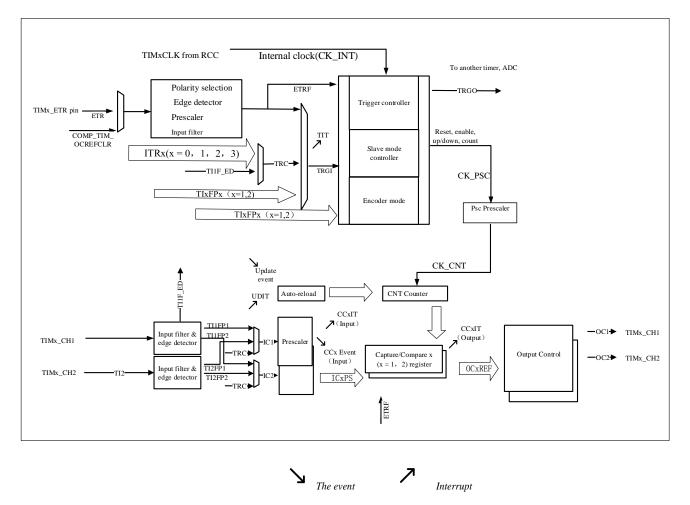

The general-purpose timers (TIM3) is mainly used in the following occasions: counting the input signal, measuring the pulse width of the input signal and generating the output waveform, etc.

9.2 Main features of General-purpose timers

- 16-bit auto-reload counters. (It can realize up-counting, down-counting, up/down counting)
- 16-bit programmable prescaler. (The frequency division factor can be configured with any value between 1 and 65536)
- TIM3 up to 2 channels
- Channel's working modes: PWM output, ouput compare, one-pulse mode output, input capture
- The events that generate the interrupt are as follows:
 - Update event
 - Trigger event
 - Input capture
 - Output compare
- Timer can be controlled by external signal
- Timers are linked internally for timer synchronization or chaining
- Supports capturing internal comparator output signals

Figure 9-1 Block diagram of TIMx (x=3)

The capture channel 1 input can come from IOM or comparator output

9.3 General-purpose timer description

9.3.1 Time-base unit

The time-base unit mainly includes: prescaler, counter and auto-reload. When the time base unit is working, the software can read and write the corresponding registers (TIMx_PSC, TIMx_CNT and TIMx_AR) at any time.

Depending on the setting of the auto-reload preload enable bit (TIMx_CTRL1.ARPEN), the value of the preload register is transferred to the shadow register immediately or at each update event UEV. An update event is generated when the counter reaches the overflow/underflow condition and it can be generated by software when TIMx_CTRL1.UPDIS=0. The counter CK_CNT is valid only when the TIMx_CTRL1.CNTEN bit is set. The counter starts counting one clock cycle after the TIMx_CTRL1.CNTEN bit is set.

9.3.1.1 Prescaler description

The TIMx_PSC register consists of a 16-bit counter that can be used to divide the counter clock frequency by any factor between 1 and 65536. It can be changed on the fly as it is buffered. The prescaler value is only taken into account at the next update event.

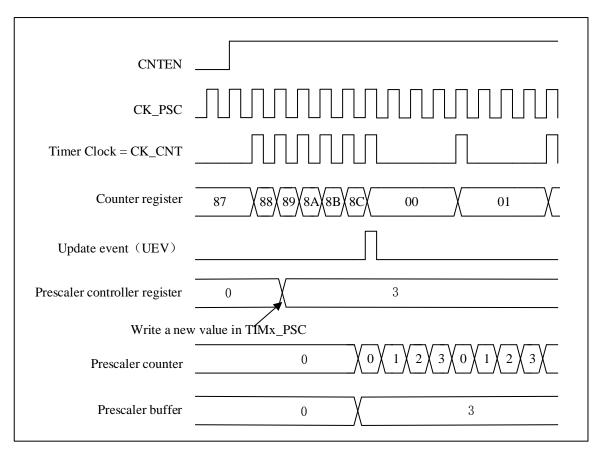

Figure 9-2 Counter timing diagram with prescaler division change from 1 to 4

9.3.2 **Counter mode**

9.3.2.1 Up-counting mode

In up-counting mode, the counter will count from 0 to the value of the register TIMx_AR, then it resets to 0. And a counter overflow event is generated.

If the TIMx_CTRL1.UPRS bit (select update request) and the TIMx_EVTGEN.UDGN bit are set, an update event (UEV) will generate And TIMx_STS.UDITF will not be set by hardware, therefore, no update interrupts are generated. This setting is used in scenarios where you want to clear the counter but do not want to generate an update interrupt.

Depending on the update request source is configured in TIMx_CTRL1.UPRS, When an update event occurs, all registers are updated and the TIMx_STS.UDITF is set:

- Update auto-reload shadow registers with preload value(TIMx_AR), when TIMx_CTRL1.ARPEN = 1.
- The prescaler shadow register is reloaded with the preload value(TIMx_PSC).

To avoid updating the shadow registers when new values are written to the preload registers, you can disable the update by setting TIMx_CTRL1.UPDIS=1.

When an update event occurs, the counter will still be cleared and the prescaler counter will also be set to 0 (but the prescaler value will remain unchanged).

The figure below shows some examples of the counter behavior and the update flags for different division factors in the up-counting mode.

9.3.2.2 **Down-counting mode**

In down-counting mode, the counter will decrement from the value of the register TIMx_AR to 0, then restart from the auto-reload value and generate a counter underflow event.

The process of configuring update events and updating registers in down-counting mode is the same as in up-counting mode, see 9.3.2.1.

The figure below shows some examples of the counter behavior and the update flags for different division factors in the down-counting mode.

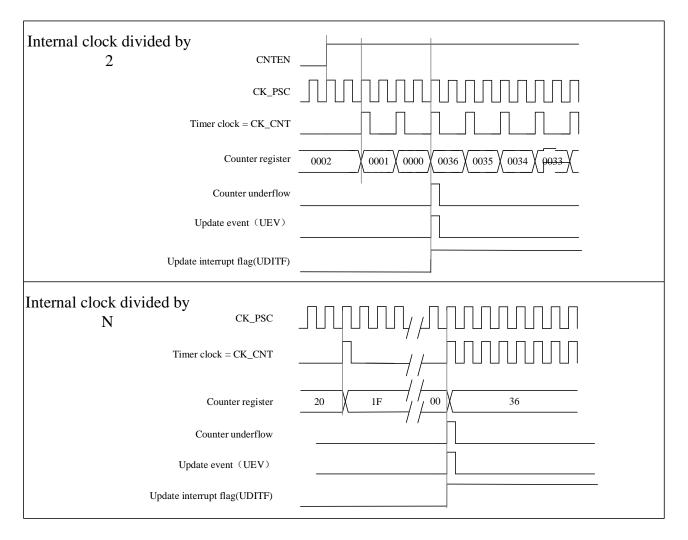

Figure 9-5 Timing diagram of the down-counting, internal clock divided factor = 2/N

9.3.2.3 Center-aligned mode

In center-aligned mode, the counter increments from 0 to the value $(TIMx_AR) - 1$, a counter overflow event is generated. It then counts down from the auto-reload value $(TIMx_AR)$ to 1 and generates a counter underflow event. Then the counter resets to 0 and starts counting up again.

In this mode, the TIMx_CTRL1.DIR direction bits have no effect and the count direction is updated and specified by hardware. Center-aligned mode is valid when the TIMx_CTRL1. CAMSEL bit is not equal to "00".

The update events can be generated each time the counter overflows and each time the counter underflows.

174 / 319

Alternatively, an update event can also be generated by setting the TIMx_EVTGEN. UDGN bit (either by software or using a slave mode controller). In this case, the counter restarts from 0, as does the prescaler's counter.

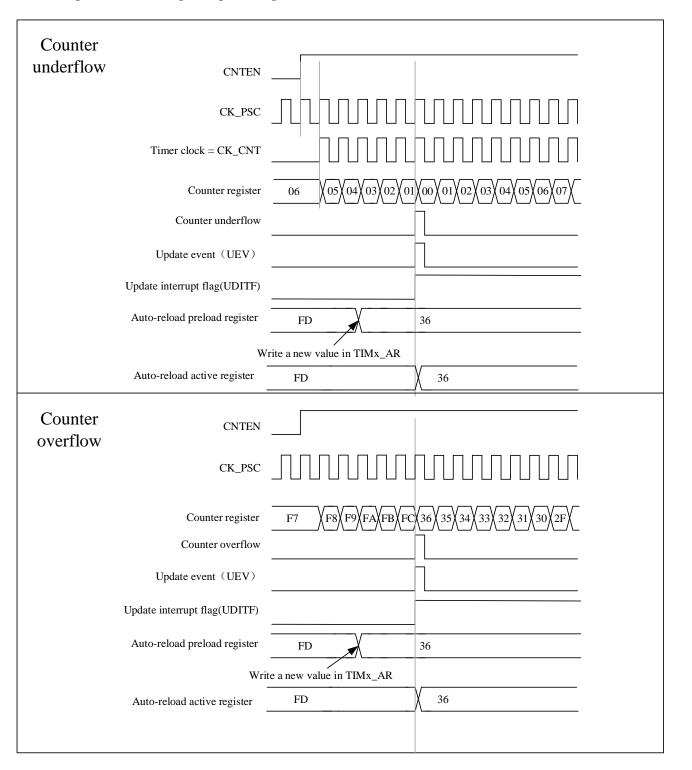

Please note: if the update source is a counter overflow, auto-reload update before reloading the counter.

9.3.3 Clock selection

- The internal clock of timers : CK_INT
- Two kinds of external clock mode :

- external input pin
- external trigger input ETR
- Internal trigger input (ITRx): one timer is used as a prescaler for another timer.

9.3.3.1 Internal clock source (CK_INT)

When the TIMx_SMCTRL.SMSEL is equal to "000", the slave mode controller is disabled. The three control bits (TIMx_CTRL1.CNTEN、TIMx_CTRL1. DIR、TIMx_EVTGEN. UDGN) can only be changed by software (except TIMx_EVTGEN. UDGN, which remains cleared automatically). It is provided that the TIMx_CTRL1.CNTEN bit is written as' 1 ' by soft, the clock source of the prescaler is provided by the internal clock CK_INT.

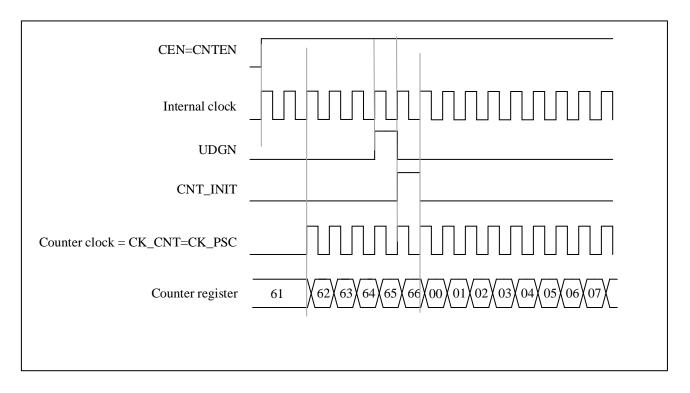

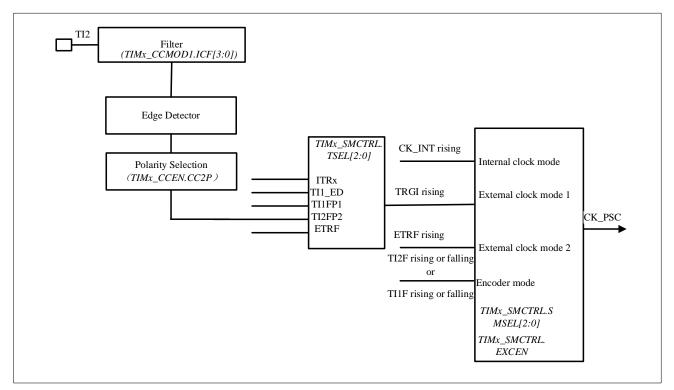

Figure 9-8 Control circuit in normal mode, internal clock divided by 1

9.3.3.2 External clock source mode 1

Figure 9-9 TI2 external clock connection example

This mode is selected by configuring TIMx_SMCTRL.SMSEL=111. The counter can be configured to count on the rising or falling edge of the clock at the selected input.

For example, to configure up-counting mode to count on the rising edge of the clock at the TI2 input, the configuration steps are as follows:

- Configure TIMx_CCMOD1.CC2SEL equal to '01', CC2 channel is configured as input, IC2 is mapped to TI2
- Configure TIMx_CCEN.CC2P equal to '0', select clock rising edge polarity
- To select input filter bandwidth by configuring TIMx_CCMOD1.IC2F[3:0] (if filter is not needed, keep IC2F bit at '0000')
- Configure TIMx_SMCTRL.SMSEL equal to '111', select timer external clock mode 1
- Configure TIMx_SMCTRL.TSEL equal to '110', select TI2 as the trigger input source
- Configure TIMx_CTRL1.CNTEN equal to '1' to start the counter

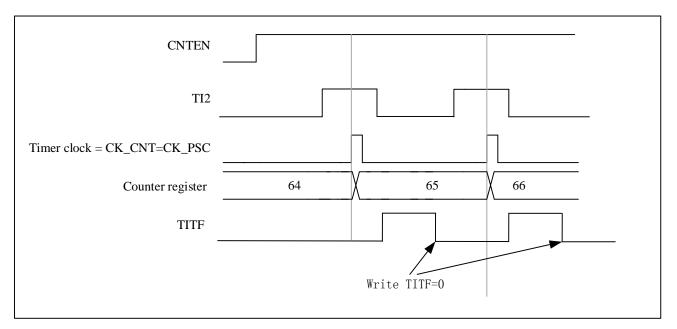

Note: The capture prescaler is not used for triggering, so it does not need to be configured

When the rising edge of the timer clock occurs at TI2=1, the counter counts once and the TIMx_STS .TITF flag is pulled high.

The delay between the rising edge of TI2 and the actual clock of the counter depends on the resynchronization circuit at the input of TI2.

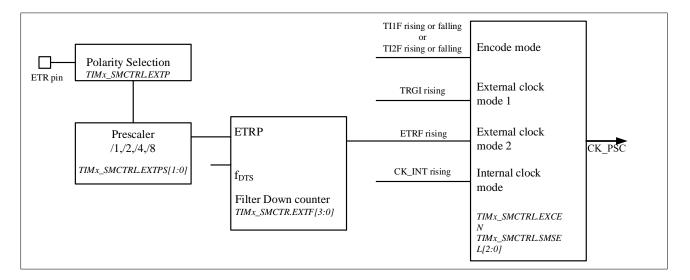

9.3.3.3 External clock source mode 2

This mode is selected by TIMx_SMCTRL.EXCEN equal to 1. The counter can count on every rising or falling edge of the external trigger input ETR.

The following figure is a schematic diagram of the external trigger input module in External clock source mode 2

Figure 9-11 External trigger input block diagram

For example, use the following configuration steps to make the up counter count every 2 rising edges on ETR.

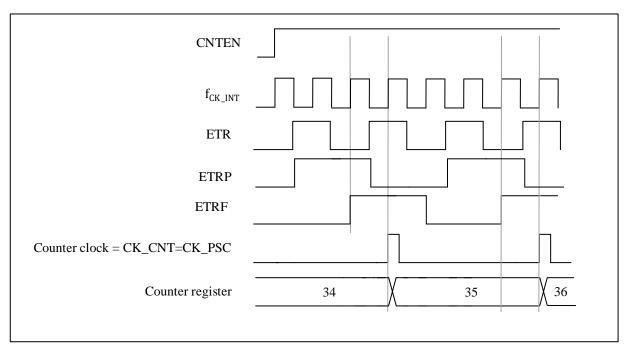

- Since no filter is needed in this case, make TIMx_SMCTRL .EXTF[3:0] equal to '0000'
- Configure the prescaler by making TIMx_SMCTRL.EXTPS[1:0] equal to '01'
- Select the polarity on ETR pin by setting TIMx_SMCTRL.EXTP equal to '0', The rising edge of ETR is valid
- External clock mode 2 is selected by setting TIMx_SMCTRL .EXCEN equal to '1'

179 / 319

■ Turn on the counter by setting TIMx_CTRL1. CNTEN equal to '1'

The counter counts every 2 rising edges of ETR. The delay between the rising edge of ETR and the actual clock to the counter is due to a resynchronization circuit on the ETRP signal.

9.3.4 Capture/compare channels

Capture/compare channels include capture/compare registers and shadow registers. The input section consists of digital filters, multiplexers and prescalers. The output section includes comparators and output controls.

The input signal TIx is sampled and filtered to generate the signal TIxF. A signal (TIxF_rising or TIxF_falling) is then generated by the edge detector of the polarity select function, the polarity of which is selected by the TIMx_CCEN.CCxP bits. This signal can be used as a trigger input for the slave mode controller. At the same time, the signal ICx is sent to the capture register after frequency division. The following figure shows a block diagram of a capture/compare channel.

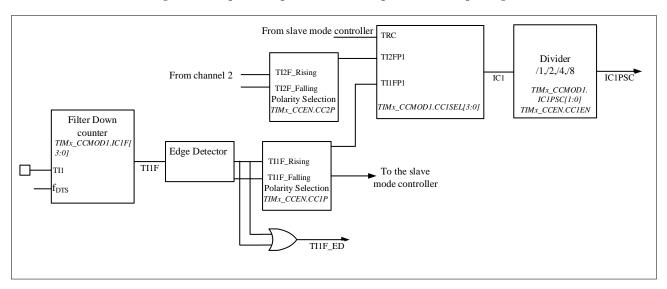

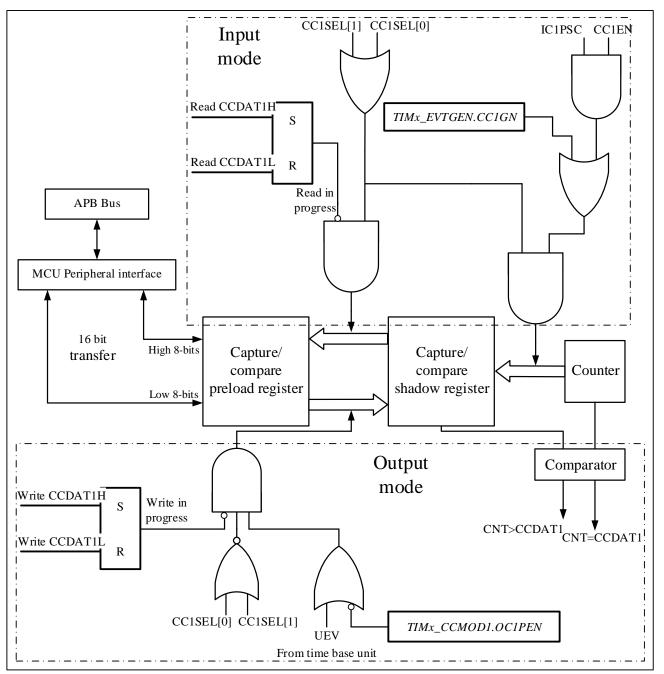

Figure 9-13 Capture/compare channel (example: channel 1 input stage)

The output part generates an intermediate waveform OCxRef (active high) as reference. The polarity acts at the end of the chain.

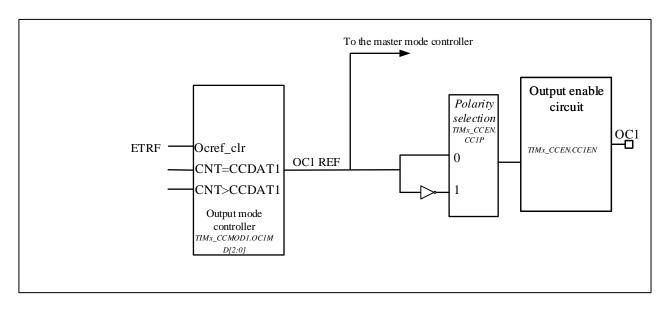

Reads and writes always access preloaded registers when capturing/comparing. The two specific working processes are as follows:

In capture mode, the capture is actually done in the shadow register, and then the value in the shadow register is copied into the preload register.

In compare mode, as opposed to capture mode, the value of the preload register is copied into the shadow register, which is compared with the counter.

9.3.5 Input capture mode

In capture mode, the TIMx_CCDATx registers are used to latch the counter value after the ICx signal detects.

There is a capture interrupt flag TIMx_STS.CCxITF, which can issue an interrupt if the corresponding interrupt enable is pulled high.

The TIMx_STS. CCxITF bit is set by hardware when a capture event occurs and is cleared by software or by reading the TIMx_CCDATx register.

The overcapture flag TIMx_STS.CCxOCF is set equal to 1 when the counter value is captured in the TIMx_CCDATx register and TIMx_STS.CC1ITF is already pulled high. Unlike the former, TIMx_STS.CCxOCF is cleared by writing 0 to it.

To achieve a rising edge of the TI1 input to capture the counter value into the TIMx_CCDAT1 register, the configuration flow is as follows:

■ To select a valid input:

Configure TIMx_CCMOD1.CC1SEL to '01'. At this time, the input is the CC1 channel, and IC1 is mapped to TI1.

■ Program the desired input filter duration:

Define the sampling frequency of the TI1 input and the length of the digital filter by configuring the

183 / 319

TIMx_CCMODx.ICxF bits. Example: If the input signal jitters up to 5 internal clock cycles, we must choose a filter duration longer than these 5 clock cycles. When 8 consecutive samples (sampled at f_{DTS} frequency) with the new level are detected, we can validate the transition on TI1. Then configure TIMx_CCMOD1. IC1F to '0011'.

- By configuring TIMx_CCEN .CC1P=0, select the rising edge as the valid transition polarity on the TI1 channel.
- Configure the input prescaler. In this example, configure TIMx_CCMOD1.IC1PSC= '00' to disable the prescaler because we want to capture every valid transition.
- Enable capture by configuring TIMx_CCEN. CC1EN = '1'.

If you want enable related interrupt request, you can configureTIMx_DINTEN.CC1IEN bit=1

9.3.6 **PWM input mode**

There are some differences between PWM input mode and normal input capture mode, including:

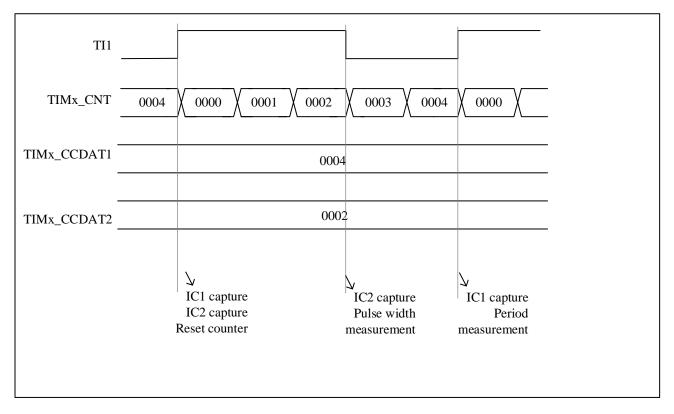

- Two ICx signals are mapped to the same TIx input.
- The two ICx signals are active on edges of opposite polarity.
- Select one of two TIxFP signals as trigger input.
- The slave mode controller is configured in reset mode.

For example, the following configuration flow can be used to know the period and duty cycle of the PWM signal on TI1 (It depends on the frequency of CK_INT and the value of the prescaler).

- Configure TIMx_CCMOD1.CC1SEL equal to '01' to select TI1 as valid input for TIMx_CCDAT1.
- Configure TIMx_CCEN.CC1P equal to '0' to select the active polarity of filtered timer input 1(TI1FP1), valid on the rising edge.
- Configure TIMx_CCMOD1.CC2SEL equal to '10' select TI1 as valid input for TIMx_CCDAT2.
- Configure TIMx_CCEN.CC2P equal to 1 to select the valid polarity of filtered timer input 2(TI1FP2), valid on the falling edge.
- Configure TIMx_SMCTRL.TSEL=101 to select Filtered timer input 1 (TI1FP1) as valid trigger input.
- Configure TIMx_SMCTRL.SMSEL=100 to configure the slave mode controller to reset mode.
- Configure TIMx_CCEN. CC1EN=1 and TIMx_CCEN.CC2EN=1 to enable capture.

Because of only filter timer input 1 (TI1FP1) and filter timer input 2 (TI2FP2) are connected to the slave mode controller, the PWM input mode can only be used with the TIMx_CH1/TIMx_CH2 signals.

9.3.7 Forced output mode

Software can force output compare signals to active or inactive level directly, in output mode (TIMx_CCMODx.CCxSEL=00).

User can set TIMx_CCMODx. OCxMD=101 to force the output compare signal to active level. And the OCxREF will be forced high, OCx get opposite value to CCxP polarity bit. On the other hand, user can set TIMx_CCMODx. OCxMD=100 to force the output compare signal to inactive level.

The values of the TIMx_CCDATx shadow register and the counter still comparing with each other in this mode. And the flag still can be set. Therefore, the interrupt still can be sent.

The comparison between the output compare register TIMx_CCDATx and the counter TIMx_CNT has no effect on OCxREF. And the flag still can be set. Therefore, the interrupt still can be sent.

9.3.8 **Output compare mode**

User can use this mode to control the output waveform, or to indicate that a period of time has elapsed.

When the capture/compare register and the counter have the same value, the output compare function's operations are as follow:

■ TIMx_CCMODx.OCxMD is for output compare mode, and TIMx_CCEN.CCxP is for output polarity. When

185 / 319

the compare matches, if set TIMx_CCMODx.OCxMD=000, the output pin will keep its level; if set TIMx_CCMODx.OCxMD=001, the output pin will be set active; if set TIMx_CCMODx.OCxMD=010, the output pin will be set inactive; if set TIMx_CCMODx.OCxMD=011, the output pin will be set to toggle.

- Set TIMx_STS.CCxITF.
- If user set TIMx_DINTEN.CCxIEN, a corresponding interrupt will be generated.

User can set TIMx_CCMODx.OCxPEN to choose capture/compare shawdow register using capture/compare preload registers(TIMx_CCDATx) or not.

The time resolution is one count of the counter.

In one pulse mode, the output compare mode can also be used to output a single pulse.

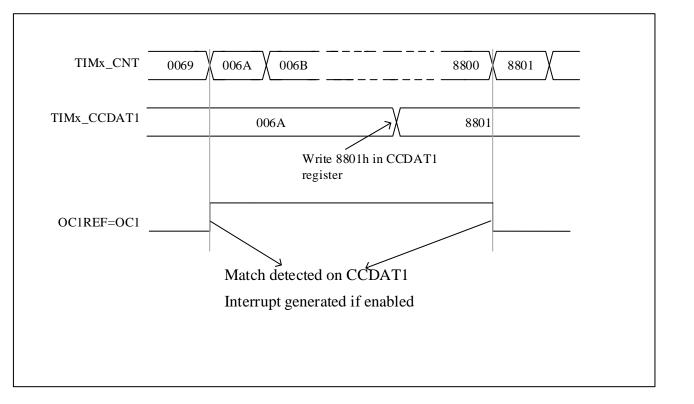

Here are the configuration steps for output compare mode:

- First of all, user should select the counter clock.
- Secondly, set TIMx_AR and TIMx_CCDATx with desired data.
- If user need to generate an interrupt, set TIMx_DINTEN.CCxIEN.
- Then select the output mode by set TIMx_CCEN.CCxP, TIMx_CCMODx.OCxMD, TIMx_CCEN.CCxEN, etc.
- At last, set TIMx_CTRL1.CNTEN to enable the counter.

User can update the output waveform by setting TIMx_CCDATx at any time, as long as the preload register is not enabled. Otherwise the TIMx_CCDATx shadow register will be updated at the next update event.

Here is an example.

Figure 9-17 Output compare mode, toggle on OC1

9.3.9 **PWM mode**

User can use PWM mode to generate a signal whose duty cycle is determined by the value of the TIMx_CCDATx register and whose frequency is determined by the value of the TIMx_AR register. And depends on the value of TIMx_CTRL1.CAMSEL, the TIM can generate PWM signal in edge-aligned mode or center-aligned mode.

User can set PWM mode 1 or PWM mode 2 by setting TIMx_CCMODx. OCxMD=110 or setting TIMx_CCMODx. OCxMD=111. To enable preload register, user must set corresponding TIMx_CCMODx.OCxPEN. And then set TIMx_CTRL1.ARPEN to auto-reload preload register eventually.

User can set polarity of OCx by setting TIMx_CCEN.CCxP. To enable the output of OCx, user need to set the combination of the value of CCxEN.

The values of TIMx_CNT and TIMx_CCDATx are always compared with each other when the TIM is under PWM mode.

Only if an update event occurs, the preload register will transfer to the shadow register. Therefore user must reset all the registers by setting TIMx_EVTGEN.UDGN before the counter starts counting.

9.3.9.1 **PWM center-aligned mode**

If user set TIMx_CTRL1.CAMSEL equal 01, 10 or 11, the PWM center-aligned mode will be active. The setting of the compare flag depends on the value of TIMx_CTRL1.CAMSEL. There are three kinds of situation that the compare flag is set, only when the counter counts up, only when the counter counts down, or when the counter counts up and counts down. User should not modified TIMx_CTRL1.DIR by software, it is updated by hardware.

Examples of center-aligned PWM waveforms is as follow, and the setting of the waveform are: TIMx_AR=8, PWM mode 1, the compare flag is set when the counter counts down corresponding to TIMx_CTRL1. CAMSEL=01.

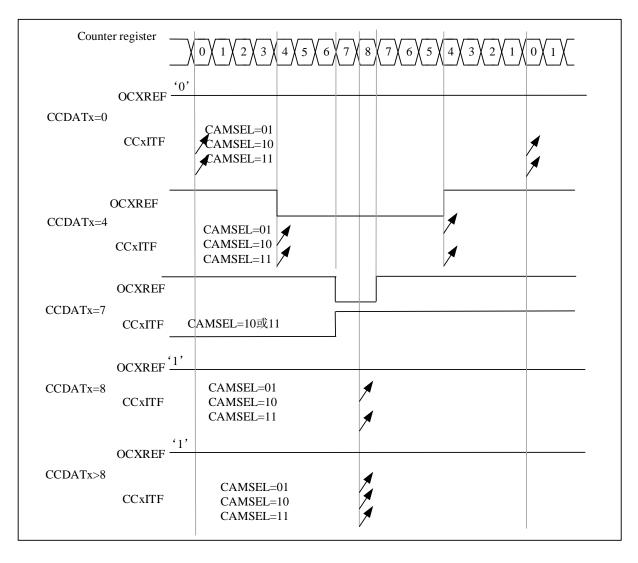

Figure 9-18 Center-aligned PWM waveform (AR=8)

Notes that user should know when using center-aligned mode are as follow:

- It depends on the value of TIMx_CTRL1.DIR that the counter counts up or down. Cautions that the DIR and CAMSEL bits should not be changed at the same time.
- User should not write the counter while running in center-aligned mode, otherwise it will cause unexpected results. Here are some example:
 - If the value written into the counter is 0 or is the value of TIMx_AR, the direction will be updated but the update event will not be generated.
 - If the value written into the counter is greater than the value of auto-reload, the direction will not be updated.
- To be on the safe side, user is suggested setting TIMx_EVTGEN.UDGN to generate an update by software before starting the counter, and not writing the counter while it is running.

9.3.9.2 **PWM edge-aligned mode**

There are two kinds of configuration in edge-aligned mode, up-counting and down-counting.

• Up-counting

User can set TIMx_CTRL1.DIR=0 to make counter counts up.

Here is an example for PWM mode1.

When $TIMx_CNT < TIMx_CCDATx$, the reference PWM signal OCxREF is high. Otherwise it will be low. If the compare value in $TIMx_CCDATx$ is greater than the auto-reload value, the OCxREF will remains 1. Conversely, if the compare value is 0, the OCxREF will remains 0.

When TIMx_AR=8, the PWM waveforms are as follow.

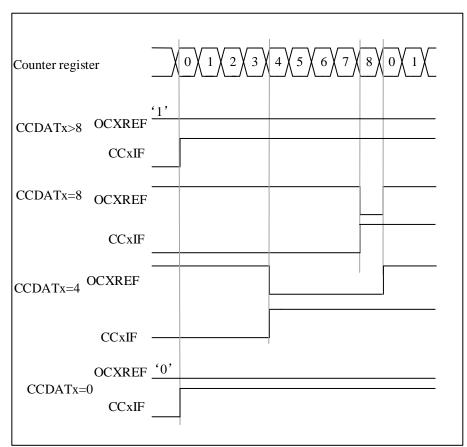

Figure 9-19 Edge-aligned PWM waveform (APR=8)

• Down-counting

User can set TIMx_CTRL1.DIR=1 to make counter counts down.

Here is an example for PWM mode1.

When $TIMx_CNT > TIMx_CCDATx$, the reference PWM signal OCxREF is low. Otherwise it will be high. If the compare value in $TIMx_CCDATx$ is greater than the auto-reload value, the OCxREF will remains 1.

Note: If the nth PWM cycle CCDATx shadow register >= AR value, the shadow register value of CCDATx in the (n+1)th PWM cycle is 0. At the moment when the counter is 0 in the (n+1)th PWM cycle, although the value of the counter = CCDATx shadow register = 0 and OCxREF = '0', no compare event will be generated.

9.3.10 **One-pulse mode**

In the one-pulse mode (ONEPM), a trigger signal is received, and a pulse tPULSE with a controllable pulse width is

189 / 319

generated after a controllable delay t_{DELAY}. The output mode needs to be configured as output compare mode or PWM mode. After selecting one-pulse mode, the counter will stop counting after the update event UEV is generated.

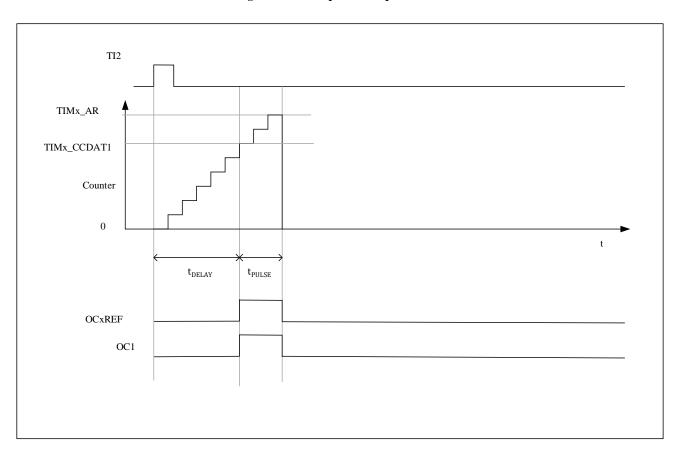

Figure 9-20 Example of One-pulse mode

The following is an example of a one-pulse mode:

A rising edge trigger is detected from the TI2 input, and a pulse with a width of t_{PULSE} is generated on OC1 after a delay of t_{DELAY} .

1. Counter configuration: count up, counter $TIMx_CNT < TIMx_CCDAT1 \le TIMx_AR$;

2. TI2FP2 is mapped to TI2, TIMx_CCMOD1.CC2SEL= '01'; TI2FP2 is configured for rising edge detection, TIMx_CCEN.CC2P= '0';

3. TI2FP2 acts as the trigger (TRGI) of the slave mode controller and starts the counter, TIMx_SMCTRL.TSEL= '110', TIMx_SMCTRL.SMSEL= '110' (trigger mode);

4. TIMx_CCDAT1 writes the count value to be delayed (t_{DELAY}), TIMx_AR - TIMx_CCDAT1 is the count value of the pulse width t_{PULSE};

5. Configure TIMx_CTRL1.ONEPM=1 to enable single pulse mode, configure TIMx_CCMOD1.OC1MD = '111' to select PWM2 mode;

6. Wait for an external trigger event on TI2, and a one pulse waveform will be output on OC1;

9.3.10.1 Special case: OCx fast enable:

In one-pulse mode, an edge is detected through the TIx input, and triggers the start of the counter to count to the

190 / 319

comparison value and then output a pulse. These operations limit the minimum delay t_{DELAY} that can be achieved.

You can set TIMx_CCMODx.OCxFEN=1 to turn on OCx fast enable, after triggering the rising edge, the OCxREF signal will be forced to be converted to the same level as the comparison match occurs immediately, regardless of the comparison result. OCxFEN fast enable only takes effect when the channel mode is configured for PWM1 and PWM2 modes.

9.3.11 Clearing the OCxREF signal on an external event

If user set TIMx_CCMODx.OCxCEN=1, high level of ETRF input can be used to driven the OCxREF signal to low, and the OCxREF signal will remains low, until the next UEV happens. Only output compare and PWM modes can use this function. This cannot be used when it is in forced mode.

Here is an example for it. To control the current, user can connect the ETR signal to the output of a comparator, and the operation for ETR should be as follow:

- Set TIMx_SMCTRL.EXTPS=00 to disable the external trigger prescaler.
- Set TIMx_SMCTRL.EXCEN=0 to disable the external clock mode 2.
- Set TIMx_SMCTRL.EXTP and TIMx_SMCTRL.EXTF to configure the external trigger polarity and external trigger filter according to the need.

Here is an example for the case that when ETRF input becomes high, the behavior of OCxREF signal for different value of OCxCEN. Timer is set to be in PWM mode in this case.

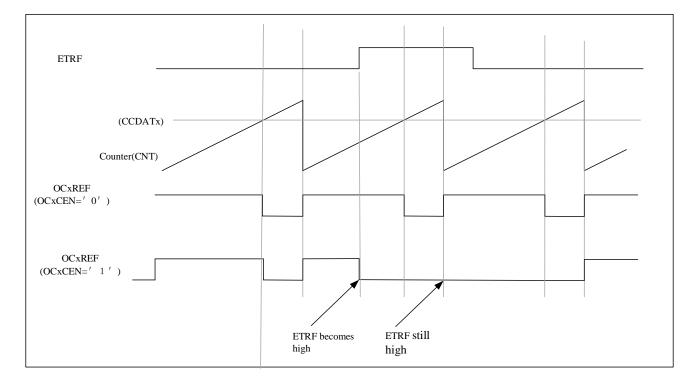

Figure 9-21 Control circuit in reset mode

9.3.12 **Debug mode**

When the microcontroller is in debug mode (the Cortex-M0 core halted), depending on the DBG_CTRL.TIMx_STOP configuration in the PWR module, the TIMx counter can either continue to work normally or stop. For more details, see 3.4.9.

9.3.13 TIMx and external trigger synchronization

Same with advanced-control timer, see 8.3.16

9.3.14 **Timer synchronization**

All TIMx timers are internally connected to each other. This implementation allows any master timer to provide trigger to reset, start, stop or provide a clock for the other slave timers. The master clock is used for internal counter and can be prescaled. Below figure shows a Block diagram of timer interconnection.

The synchronization function does not support dynamic change of the connection. User should configure and enable the slave timer before enable the master timer's trigger or clock.

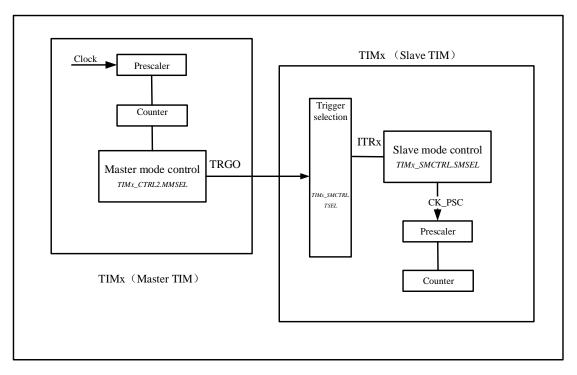

Figure 9-22 Block diagram of timer interconnection

9.3.14.1 Master timer as a prescaler for another timer

TIM1 as a prescaler for TIM3. TIM1 is maser, TIM3 is slave.

User need to do the following steps for this configuration.

■ Setting TIM1_CTRL2.MMSEL=' 010' to use the update event of TIM1 as trigger output.

192 / 319

- Configure TIM3_SMCTRL. TSEL= '000', connect the TRGO of TIM1 to TIM3.
- Configure TIM3_SMCTRL.SMSEL = '111', the slave mode controller will be configured in external clock mode 1.
- Start TIM3 by setting TIM3_CTRL1. CNTEN = '1'.
- Start TIM1 by setting TIM1_CTRL1. CNTEN = '1'.

Note: If user select OCx as the trigger output of TIM1 by configuring MMSEL = '1xx', OCx rising edge will be used to drive TIM3.

9.3.14.2 Master timer to enable another timer

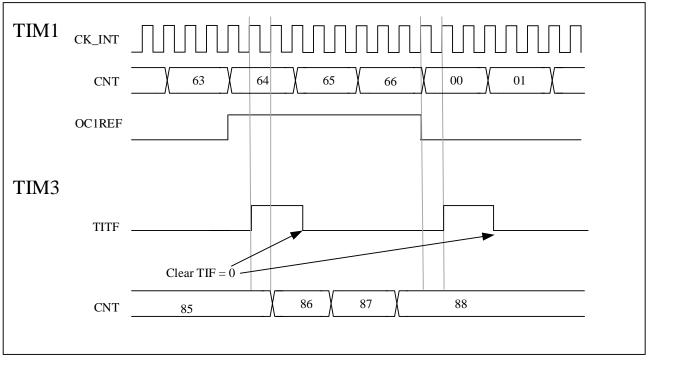

In this example, TIM3 is enabled by the output compare of TIM1. TIM3 counter will start to count after the OC1REF output from TIM1 is high. Both counters are clocked based on CK_INT via a prescaler divide by 3 is performed ($f_{CK_CNT} = f_{CK_INT}/3$).

The configuration steps are shown as below.

- Setting TIM1_CTRL2.MMSEL='100' to use the OC1REF of TIM1 as trigger output.
- Configure TIM1_CCMOD1 register to configure the OC1REF output waveform.
- Setting TIM3_SMCTRL.TSEL = '000' to connect TIM1 trigger output to TIM3.
- Setting TIM3_SMCTRL.SMSEL= '101' to set TIM3 to gated mode.
- Setting TIM3_CTRL1.CNTEN= '1' to start TIM3.
- Setting TIM1_CTRL1.CNTEN= '1' to start TIM1.

Note: The TIM3 clock is not synchronized with the TIM1 clock, this mode only affects the TIM3 counter enable signal.

Figure 9-23 TIM3 gated by OC1REF of TIM1

Nations Technologies Inc. Tel: +86-755-86309900 Email: info@nationstech.com Address: Nations Tower, #109 Baoshen Road, Hi-tech Park North. Nanshan District, Shenzhen, 518057, P.R.China

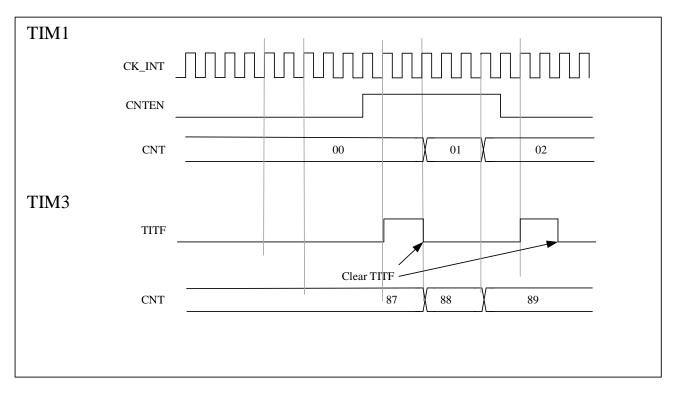

In the next example, Gated TIM3 with enable signal of TIM1, Setting TIM1.CTRL1.CNTEN = '0' to stop TIM1. TIM3 counts on the divided internal clock only when TIM1 is enable. Both counters are clocked based on CK_INT via a prescaler divide by 3 is performed ($f_{CK_{CNT}} = f_{CK_{INT}/3}$).

The configuration steps are shown as below

- Setting TIM1_CTRL2.MMSEL='001' to use the enable signal of TIM1 as trigger output
- Setting TIM3_SMCTRL.TSEL = '000' to configure TIM3 to get the trigger input from TIM1
- Setting TIM3_SMCTRL.SMSEL = '101' to configure TIM3 in gated mode.
- Setting TIM3_CTRL1.CNTEN= '1' to start TIM3.
- Setting TIM1_CTRL1.CNTEN= '1' to start TIM1.
- Setting TIM1_CTRL1.CNTEN= '0' to stop TIM1.

Figure 9-24 TIM3 gated by enable signal of TIM1

9.3.14.3 Master timer to start another timer

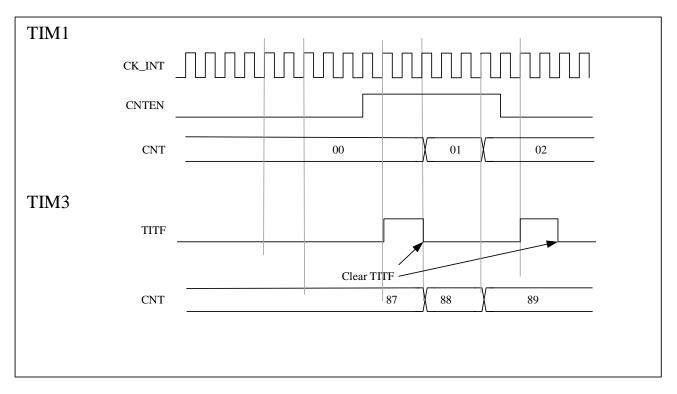

In this example, we can use update event as trigger source.TIM1 is master, TIM3 is slave.

The configuration steps are shown as below:

- Setting TIM1_CTRL2.MMSEL=' 010' to use the update event of TIM1 as trigger output
- Configure TIM1_AR register to set the output period.
- Setting TIM3_SMCTRL .TSEL= '000' to connect TIM1 trigger output to TIM3.
- Setting TIM3_SMCTRL. SMSEL = '110' to set TIM3 to trigger mode.
- Setting TIM1_CTRL1.CNTEN=1 to start TIM1.

9.3.14.4 Start 2 timers synchronously using an external trigger

In this example, TIM1 is enabled when TIM1's TI1 input rises, and TIM3 is enabled when TIM1 is enabled. To ensure the alignment of counters, TIM1 must be configured in master/slave mode. For TI1, TIM1 is the slave; for TIM3, TIM1 is the master.

The configuration steps are shown as below:

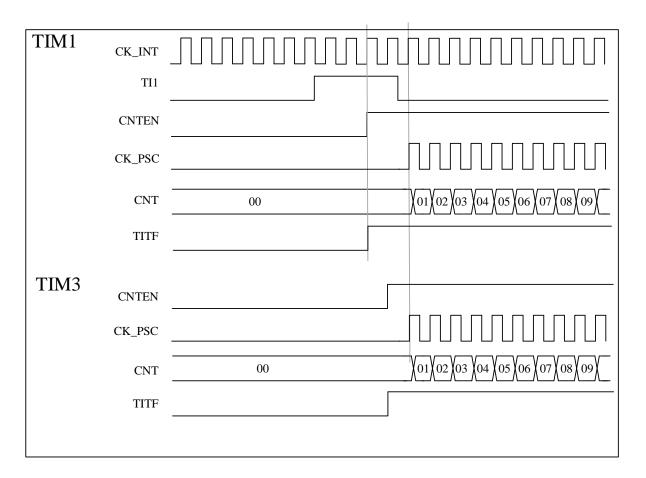

- Setting TIM1.MMSEL = '001' to use the enable signal as trigger output
- Setting TIM1_SMCTRL.TSEL = '100' to configure the TIM1 to slave mode and receive the trigger input of TI1.
- Setting TIM1_SMCTRL .SMSEL = '110' to configure TIM1 to trigger mode.
- Setting TIM1_SMCTRL .MSMD = '1' to configure TIM1 to master/slave mode.
- Setting TIM3_SMCTRL .TSEL = '000' to connect TIM1 trigger output to TIM3.
- Setting TIM3_SMCTRL.SMSEL = '110' to configure TIM3 to trigger mode.

When TI1 rising edge arrives, both timers start counting synchronously according to the internal clock, and both TITF flags are set simultaneously.

The following figure shows a delay between CNTEN and CK_PSC of TIM1 in master/slave mode.

Bit field	Name	Description
11	C1SEL	Channel 1 selection
		0: Select external CH1 signal from IOM
		1: Select internal CH1 signal from COMP
10	Reserved	Reserved, the reset value must be maintained
9:8	CLKD[1:0]	Clock division
		CLKD[1:0] indicates the division ratio between CK_INT (timer clock) and t _{DTS} (clock used
		for dead-time generator and digital filters (ETR, TIx))
		00: $t_{DTS} = t_{CK_INT}$
		01: $t_{DTS} = 2 \times t_{CK_{INT}}$
		10: $t_{DTS} = 4 \times t_{CK_INT}$
		11: Reserved, do not use this configuration
7	ARPEN	ARPEN: Auto-reload preload enable
		0: Shadow register disable for TIMx_AR register
		1: Shadow register enable for TIMx_AR register
6:5	CAMSEL[1:0]	Center-aligned mode selection
		00: Edge-aligned mode. TIMx_CTRL1.DIR specifies up-counting or down-counting.
		01: Center-aligned mode 1. The counter counts in center-aligned mode, and the output
		compare interrupt flag bit is set to 1 when down-counting.
		10: Center-aligned mode 2. The counter counts in center-aligned mode, and the output
		compare interrupt flag bit is set to 1 when up-counting.
		11: Center-aligned mode 3. The counter counts in center-aligned mode, and the output
		compare interrupt flag bit is set to 1 when up-counting or down-counting.
		Note: Switching from edge-aligned mode to center-aligned mode is not allowed when the
		counter is still enabled ($TIMx_CTRL1.CNTEN = 1$).
4	DIR	Direction
		0: Up-counting
		1: Down-counting
		Note: This bit is read-only when the counter is configured in center-aligned mode.
3	ONEPM	One-pulse mode
		0: Disable one-pulse mode, the counter counts are not affected when an update event occurs.
		1: Enable one-pulse mode, the counter stops counting when the next update event occurs
		(clearing TIMx_CTRL1.CNTEN bit)
2	UPRS	Update request source
		This bit is used to select the UEV event sources by software.
		0: If update interrupt is enabled, any of the following events will generate an update interrupt:
		– Counter overflow/underflow
		 The TIMx_EVTGEN.UDGN bit is set
		 Update generation from the slave mode controller
		1: If update interrupt is enabled, only counter overflow/underflow will generate update
		interrupt

Bit field	Name	Description				
1	UPDIS	Update disable				
		This bit is used to enable/disable the Update event (UEV) events generation by software.				
		0: Enable UEV. And UEV will be generated if one of following condition been fulfilled:				
		- Counter overflow/underflow				
		 The TIMx_EVTGEN.UDGN bit is set 				
		 Update generation from the slave mode controller 				
		Shadow registers will update with preload value.				
		1: UEV disabled. No update event is generated, and the shadow registers (AR, PSC, and				
		CCDATx) keep their values. If the TIMx_EVTGEN.UDGN bit is set or a hardware reset is				
		issued by the slave mode controller, the counter and prescaler are reinitialized.				
0	CNTEN	Counter Enable				
		0: Disable counter				
		1: Enable counter				
		Note: external clock, gating mode can only work after TIMx_CTRL1.CNTEN bit is set in the				
		software. Trigger mode can automatically set TIMx_CTRL1.CNTEN bit by hardware.				

9.4.3 Control register 2 (TIMx_CTRL2)

Offset address: 0x04

Bit field	Name	Description					
15:9	Reserved	Reserved, the reset value must be maintained					
8	ETRSEL	External Triggered Selection storage (ETR Selection)					
		0: Select external ETR (from IOM) signal;					
		1: Reserved					
7	Reserved	Reserved, the reset value must be maintained					
6:4	MMSEL[2:0]	Master Mode Selection					
		These 3 bits (TIMx_CTRL2. MMSEL [2:0]) are used to select the synchronization information					
		(TRGO) sent to the slave timer in the master mode. Possible combinations are as follows:					
		000: Reset -When the TIMx_EVTGEN.UDGN is set or a reset is generated by the slave mode					
		controller, a TRGO pulse occurs. And in the latter case, the signal on TRGO is delayed					
		compared to the actual reset.					
		001: Enable - The TIMx_CTRL1.CNTEN bit is used as the trigger output (TRGO). Sometimes					
		you need to start multiple timers at the same time or enable slave timer for a period of time.					

Bit field	Name	Description
		The counter enable signal is set when TIMx_CTRL1.CNTEN bit is set or the trigger input in
		gated mode is high.
		When the counter enable signal is controlled by the trigger input, there is a delay on TRGO
		except if the master/slave mode is selected (see the description of the TIMx_SMCTRL.MSMD
		bit).
		010: Update - The update event is selected as the trigger output (TRGO). For example, a master
		timer clock can be used as a slave timer prescaler.
		011: Compare pulse - Triggers the output to send a positive pulse (TRGO) when the
		TIMx_STS.CC1ITF is to be set (even if it is already high), when a capture or a comparison
		succeeds.
		100: Compare - OC1REF signal is used as the trigger output (TRGO).
		101: Compare - OC2REF signal is used as the trigger output (TRGO).
		Others: reserved
3:0	Reserved	Reserved, the reset value must be maintained

9.4.4 Slave mode control register (TIMx_SMCTRL)

Offset address: 0x08

15	14	13 12	11	8	7	6	4	3	2	0
EXTP	EXCEN	EXTPS[1:0]	EXTF[3:0]	1	MSMD	TSEL[2:0]		Reserved		SMSEL[2:0]
rw	rw	rw	rw		rw	rw				rw

Bit field	Name	Description
15 EXTP		External trigger polarity
		This bit is used to select whether the trigger operation is to use ETR or the inversion of ETR.
		0: ETR active at high level or rising edge.
		1: ETR active at low level or falling edge.
14	EXCEN	External clock enable
		This bit is used to enable external clock mode 2, and the counter is driven by any active edge on
		the ETRF signal in this mode.
		0: External clock mode 2 disable.
		1: External clock mode 2 enable.
		Note 1: When external clock mode 1 and external clock mode 2 are enabled at the same time, the
		input of the external clock is ETRF.
		Note 2: The following slave modes can be used simultaneously with external clock mode 2: reset
		mode, gated mode and trigger mode; However, TRGI cannot connect to ETRF
		$(TIMx_SMCTRL.TSEL \neq '111').$
		Note 3: Setting the TIMx_SMCTRL.EXCEN bit has the same effect as selecting external clock
		mode 1 and connecting TRGI to ETRF (TIMx_SMCTRL.SMSEL = 111 and TIMx_SMCTRL.TSEL
		= 111).

Bit field	Name	Description
13:12	EXTPS[1:0]	External trigger prescaler
		The frequency of the external trigger signal ETRP must be at most 1/4 of TIMxCLK frequency.
		When a faster external clock is input, a prescaler can be used to reduce the frequency of ETRP.
		00: Prescaler disable
		01: ETRP frequency divided by 2
		10: ETRP frequency divided by 4
		11: ETRP frequency divided by 8
11:8	EXTF[3:0]	External trigger filter
		These bits are used to define the frequency at which the ETRP signal is sampled and the
		bandwidth of the ETRP digital filtering. In effect, the digital filter is an event counter that
		generates a validate output after consecutive N events are recorded.
		0000: No filter, sampling at f _{DTS}
		0001: $f_{SAMPLING} = f_{CK_INT}$, N = 2
		0010: $f_{\text{SAMPLING}} = f_{\text{CK_INT}}$, N = 4
		0011: $f_{SAMPLING} = f_{CK_INT}$, N = 8
		0100: $f_{SAMPLING} = f_{DTS}/2$, N = 6
		0101: $f_{SAMPLING} = f_{DTS}/2, N = 8$
		0110: $f_{SAMPLING} = f_{DTS}/4$, N = 6
		0111: $f_{\text{SAMPLING}} = f_{\text{DTS}}/4$, N = 8
		1000: $f_{SAMPLING} = f_{DTS}/8$, N = 6
		1001: $f_{SAMPLING} = f_{DTS}/8$, N = 8
		1010: $f_{SAMPLING} = f_{DTS}/16$, N = 5
		1011: $f_{SAMPLING} = f_{DTS}/16$, N = 6
		1100: $f_{SAMPLING} = f_{DTS}/16$, N = 8
		1101: $f_{SAMPLING} = f_{DTS}/32$, N = 5
		1110: $f_{SAMPLING} = f_{DTS}/32$, N = 6
		1111: $f_{SAMPLING} = f_{DTS}/32$, N = 8
7	MSMD	Master/ Slave mode
		0: No action
		1: Events on the trigger input (TRGI) are delayed to allow a perfect synchronization between the
		current timer (via TRGO) and its slaves. This is useful when several timers are required to be
		synchronized to a single external event.
5:4	TSEL[2:0]	Trigger selection
		These 3 bits are used to select the trigger input of the synchronous counter.
		000: Internal trigger 0 (ITR0) 100: TI1 edge detector (TI1F_ED)
		001: Internal trigger 1 (ITR1) 101: Filtered timer input 1(TI1FP1)
		010: Internal trigger 2 (ITR2) 110: Filtered timer input 2 (TI2FP2)
		011: Internal trigger 3 (ITR3) 111: External triggered Input (ETRF)
		For more details on ITRx, see Table 9-2 below.
		Note: These bits must be changed only when not in use (e. g. TIMx_SMCTRL.SMSEL=000) to
		avoid false edge detection at the transition.
3	Reserved	Reserved, the reset value must be maintained

Bit field	Name	Description
2:0	SMSEL[2:0]	Slave mode selection
		When an external signal is selected, the active edge of the trigger signal (TRGI) is linked to the
		selected external input polarity (see input control register and control register description)
		000: Disable slave mode. If TIMx_CTRL1.CNTEN = 1, the prescaler is driven directly by the
		internal clock.
		001: reserved.
		010: reserved.
		011: reserved.
		100: Reset mode. On the rising edge of the selected trigger input (TRGI), the counter is
		reinitialized and the shadow register is updated.
		101: Gated mode. When the trigger input (TRGI) is high, the clock of the counter is enabled. Once
		the trigger input becomes low, the counter stops counting, but is not reset. In this mode, the start
		and stop of the counter are controlled.
		110: Trigger mode. When a rising edge occurs on the trigger input (TRGI), the counter is started
		but not reset. In this mode, only the start of the counter is controlled.
		111: External clock mode 1. The counter is clocked by the rising edge of the selected trigger input
		(TRGI).
		Note: Do not use gated mode if TIIF_ED is selected as the trigger input
		(TIMx_SMCTRL.TSEL=100). This is because TI1F_ED outputs a pulse for each TI1F transition,
		whereas gated mode checks the level of the triggered input.

Table 9-2 TIM	internal	trigger	connection
---------------	----------	---------	------------

		0: Disable update interrupt
		1: Enables update interrupt

9.4.6 Status registers (TIMx_STS)

Offset address: 0x10

	15				11	10	9	8	7	6	5		3	2	1	0
		I	Reserved	I	1	CC2OCF	CC10CF	Rese	erved	TITF		Reserved		CC2ITF	CC1ITF	UDITF
I						rc_w0	rc_w0			rc_w0				rc_w0	rc_w0	rc_w0

Bit field	Name	Description
15:11	Reserved	Reserved, the reset value must be maintained
10	CC2OCF	Capture/Compare 2 overcapture flags
		See TIMx_STS.CC1OCF description.
9	CC10CF	Capture/Compare 1 overcapture flag
		This bit is set by hardware only when the corresponding channel is configured in input capture
		mode. Cleared by software writing 0.
		0: No overcapture occurred
		1: TIMx_STS.CC1ITF was already set when the value of the counter has been captured in the
		TIMx_CCDAT1 register.
8:7	Reserved	Reserved, the reset value must be maintained
6	TITF	Trigger interrupt flag
		This bit is set by hardware when an active edge is detected on the TRGI input when the slave
		mode controller is in a mode other than gated. This bit is set by hardware when any edge in
		gated mode is detected. This bit is cleared by software.
		0: No trigger event occurred
		1: Trigger interrupt occurred
5:3	Reserved	Reserved, the reset value must be maintained
2	CC2ITF	Capture/Compare 2 interrupt flag
		See TIMx_STS.CC1ITF description.
1	CC1ITF	Capture/Compare 1 interrupt flag
		When the corresponding channel of CC1 is in output mode:

Bit field	Name	Description
		Except in center-aligned mode, this bit is set by hardware when the counter value is the same as
		the compare value (see TIMx_CTRL1.CAMSEL bit description). This bit is cleared by
		software.
		0: No match occurred.
		1: The value of TIMx_CNT is the same as the value of TIMx_CCDAT1.
		When the value of TIMx_CCDAT1 is greater than the value of TIMx_AR, the
		TIMx_STS.CC1ITF bit will go high if the counter overflows (in up-counting and up/down-
		counting modes) and underflows in down-counting mode.
		When the corresponding channel of CC1 is in input mode:
		This bit is set by hardware when the capture event occurs. This bit is cleared by software or by
		reading TIMx_CCDAT1.
		0: No input capture occurred.
		1: Input capture occurred. Counter value has captured in the TIMx_CCDAT1. An edge with the
		same polarity as selected has been detected on IC1.
0	UDITF	Update interrupt flag
		This bit is set by hardware when an update event occurs under the following conditions:
		- When TIMx_CTRL1.UPDIS = 0, overflow or underflow (An update event is generated).
		- When TIMx_CTRL1.UPRS = 0, TIMx_CTRL1.UPDIS = 0, and set the
		TIMx_EVTGEN.UDGN bit by software to reinitialize the CNT.
		- When TIMx_CTRL1.UPRS = 0, TIMx_CTRL1.UPDIS = 0, and the counter CNT is
		reinitialized by the trigger event. (See TIMx_SMCTRL Register description)
		This bit is cleared by software.
		0: No update event occurred
		1: Update interrupt occurred

9.4.7 Event generation registers (TIMx_EVTGEN)

Offset address: 0x14

 15	 			_		7	6	5		3	2	1	0
			Reserved				TGN		Reserved		CC2GN	CC1GN	UDGN
	 	I					w				w	w	w

Bit field	Name	Description
15: 7	Reserved	Reserved, the reset value must be maintained.
6	TGN	Trigger generation
		This bit can generate a trigger event when set by software. And at this time TIMx_STS.TITF =
		1, if the corresponding interrupt are enabled, the corresponding interrupt will be generated. This
		bit is automatically cleared by hardware.
		0: No action
		1: Generated a trigger event
5:3	Reserved	Reserved, the reset value must be maintained

Bit field	Name	Description
2	CC2GN	Capture/Compare 2 generation
		See TIMx_EVTGEN.CC1GN description.
1	CC1GN	Capture/Compare 1 generation
		This bit can generate a capture/compare event when set by software. This bit is automatically
		cleared by hardware.
		When the corresponding channel of CC1 is in output mode:
		The TIMx_STS.CC1ITF flag will be pulled high, if the corresponding interrupt are enabled, the
		corresponding interrupt will be generated.
		When the corresponding channel of CC1 is in input mode:
		TIMx_CCDAT1 will capture the current counter value, and the TIMx_STS.CC1ITF flag will be
		pulled high, if the corresponding interrupt are enabled, the corresponding interrupt will be
		generated. If The IMx_STS.CC1ITF is already pulled high, pull TIMx_STS.CC1OCF high.
		0: No action
		1: Generated a CC1 capture/compare event
0	UDGN	Update generation
		This bit can generate an update event when set by software. And at this time the counter will be
		reinitialized, the prescaler counter will be cleared, the counter will be cleared in center-aligned or up-
		counting mode, but take TIMx_AR in down-counting mode the value of the register. This bit is
		automatically cleared by hardware.
		0: No action
		1: Generated an update event

9.4.8 Capture/compare mode register 1 (TIMx_CCMOD1)

Offset address: 0x18

Reset value: 0x0000

Channels can be used for input (capture mode) or output (compare mode), and the direction of the channel is defined by the corresponding CCxSEL bit. The other bits of the register act differently in input and output modes. OCx describes the function of a channel in output mode, ICx describes the function of a channel in input mode. Hence, please note that the same bit can have different meanings for output mode and for input mode.

Output compare mode:

15		14		12	11	10	9	8	7	6		4	3	2	1	0
OC2CE	^I N	(DC2MD[2:0]	OC2PEN	OC2FEN	CC2SE	EL[1:0]	OC1CEN		OC1MD[2:0]		OC1PEN	OC1FEN	CC1SI	EL[1:0]
rw			rw		rw	rw	rv	N	rw		rw		rw	rw	r	w

Bit field	Name	Description						
15	OC2CEN	Output Compare 2 clear enable						
14:12	OC2MD[2:0]	Output Compare 2 mode						
11	OC2PEN	Output Compare 2 preload enable						
10	OC2FEN	Output Compare 2 fast enable						

Bit field	Name	Description						
9:8	CC2SEL[1:0]	Capture/compare 2 selection						
		These bits are used to select the input/output and input mapping of the channel						
		00: CC2 channel is configured as output						
		01: CC2 channel is configured as input, IC2 is mapped on TI2						
		10: CC2 channel is configured as input, IC2 is mapped on TI1						
		11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode is only active						
		when the internal trigger input is selected by TIMx_SMCTRL.TSEL.						
		Note: CC2SEL is writable only when the channel is off ($TIMx_CCEN.CC2EN = 0$).						
7	OC1CEN	Output Compare 1 clear enable						
		0: OC1REF is not affected by ETRF input level						
		1: OC1REF is cleared immediately when the ETRF input level is detected as high						
6:4	OC1MD[2:0]	Output Compare 1 mode						
		These bits are used to manage the output reference signal OC1REF, which determines the						
		values of OC1 and OC1N, and is valid at high levels, while the active levels of OC1 and						
		OC1N depend on the TIMx_CCEN.CC1P and TIMx_CCEN.CC1NP bits.						
		000: Frozen. Comparison between TIMx_CCDAT1 register and counter TIMx_CNT has no						
		effect on OC1REF signal.						
		001: Set channel 1 to the active level on match. When $TIMx_CCDAT1 = TIMx_CNT$,						
		OC1REF signal will be forced high.						
		010: Set channel 1 as inactive level on match. When $TIMx_CCDAT1 = TIMx_CNT$,						
		OC1REF signal will be forced low.						
		011: Toggle. When TIMx_CCDAT1 = TIMx_CNT, OC1REF signal will be toggled.						
		100: Force to inactive level. OC1REF signal is forced low.						
		101: Force to active level. OC1REF signal is forced high.						
		110: PWM mode 1 - In up-counting mode, if TIMx_CNT < TIMx_CCDAT1, OC1REF signal						
		of channel 1 is high, otherwise it is low. In down-counting mode, if TIMx_CNT >						
		TIMx_CCDAT1, OC1REF signal of channel 1 is low, otherwise it is high.						
		111: PWM mode 2 - In up-counting mode, if TIMx_CNT < TIMx_CCDAT1, OC1REF signal						
		of channel 1 is low, otherwise it is high. In down-counting mode, if TIMx_CNT >						
		TIMx_CCDAT1, OC1REF signal of channel 1 is high, otherwise it is low.						
		Note 1: In PWM mode 1 or PWM mode 2, the OC1REF level changes only when the						
		comparison result changes or when the output compare mode is switched from frozen mode to						
		PWM mode.						
3	OC1PEN	Output Compare 1 preload enable						
5	o chi Liv	0: Disable preload function of TIMx_CCDAT1 register. Supports write operations to						
		TIMx_CCDAT1 register at any time, and the written value is effective immediately.						
		1: Enable preload function of TIMx_CCDAT1 register. Only read and write operations to						
		preload registers. When an update event occurs, the value of TIMx_CCDAT1 is loaded into						
		the active register.						
		<i>Note 1: Only when TIMx_CTRL1.ONEPM = 1(In one-pulse mode), PWM mode can be used</i>						
		without verifying the preload register, otherwise no other behavior can be predicted.						

Bit field	Name	Description						
2	OC1FEN	Output Compare 1 fast enable						
		This bit is used to speed up the response of the CC output to the trigger input event.						
		0: CC1 behaves normally depending on the counter and CCDAT1 values, even if the trigger is						
		ON. The minimum delay for activating CC1 output when an edge occurs on the trigger input						
		is 5 clock cycles.						
		1: An active edge of the trigger input acts like a comparison match on CC1 output. Therefore,						
		OC is set to the comparison level regardless of the comparison result. The delay time for						
		sampling the trigger input and activating the CC1 output is reduced to 3 clock cycles.						
		OCxFEN only works if the channel is configured in PWM1 or PWM2 mode.						
1: 0	CC1SEL[1:0]	Capture/compare 1 selection						
		These bits are used to select the input/output and input mapping of the channel						
		00: CC1 channel is configured as output						
		01: CC1 channel is configured as input, IC1 is mapped on TI1						
		10: CC1 channel is configured as input, IC1 is mapped on TI2						
		11: CC1 channels are configured as inputs and IC1 is mapped to TRC. This mode is only						
		active when the internal trigger input is selected by TIMx_SMCTRL.TSEL.						
		Note: CC1SEL is writable only when the channel is off $(TIMx_CCEN.CC1EN = 0)$.						

Input capture mode:

15	12	11	10	9	8	7		4	3	2	1	0
IC2F[3:0]	I	IC2PSC[1	:0]	CC2SE	EL[1:0]		IC1F[3:0]	1	IC1PS	C[1:0]	CC1SE	EL[1:0]
		· · ·	-

Bit field	Name	Description						
15:12	IC2F[3:0]	Input Capture 2 Filter						
11:10	IC2PSC[1:0]	nput Capture 2 Prescaler						
9:8	CC2SEL[1:0]	Capture/Compare 2 selection						
		These bits are used to select the input/output and input mapping of the channel						
		00: CC2 channel is configured as output						
		01: CC2 channel is configured as input, IC2 is mapped on TI2						
		10: CC2 channel is configured as input, IC2 is mapped on TI1						
		11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode is only active when						
		the internal trigger input is selected by TIMx_SMCTRL.TSEL.						
		Note: CC2SEL is writable only when the channel is off $(TIMx_CCEN.CC2EN = 0)$.						
7:4	IC1F[3:0]	Input Capture 1 filter						
		These bits are used to define sampling frequency of TI1 input and the length of digital filter. The						
		digital filter is an event counter that generates an output transition after N events are recorded.						
		0000: No filter, sampling at fDTS frequency						
		0001: $f_{SAMPLING} = f_{CK_INT}$, N = 2						
		0010: $f_{SAMPLING} = f_{CK_INT}$, N = 4						
		0011: $f_{SAMPLING} = f_{CK_INT}$, N = 8						

Bit field	Name	Description
		0100: $f_{SAMPLING} = f_{DTS}/2$, N = 6
		0101: $f_{SAMPLING} = f_{DTS}/2$, N = 8
		0110: $f_{SAMPLING} = f_{DTS}/4$, N = 6
		0111: $f_{SAMPLING} = f_{DTS}/4$, N = 8
		1000: $f_{SAMPLING} = f_{DTS}/8$, N = 6
		$1001: f_{SAMPLING} = f_{DTS}/8, N = 8$
		1010: $f_{SAMPLING} = f_{DTS}/16$, N = 5
		$1011: f_{SAMPLING} = f_{DTS}/16, N = 6$
		1100: $f_{SAMPLING} = f_{DTS}/16$, N = 8
		1101: $f_{SAMPLING} = f_{DTS}/32$, N = 5
		1110: $f_{SAMPLING} = f_{DTS}/32$, N = 6
		1111: $f_{SAMPLING} = f_{DTS}/32$, N = 8
3:2	IC1PSC[1:0]	Input Capture 1 prescaler
		These bits are used to select the ratio of the prescaler for IC1 (CC1 input).
		When $TIMx_CCEN.CC1EN = 0$, the prescaler will be reset.
		00: No prescaler, capture is done each time an edge is detected on the capture input
		01: Capture is done once every 2 events
		10: Capture is done once every 4 events
		11: Capture is done once every 8 events
1:0	CC1SEL[1:0]	Capture/Compare 1 selection
		These bits are used to select the input/output and input mapping of the channel
		00: CC1 channel is configured as output
		01: CC1 channel is configured as input, IC1 is mapped on TI1
		10: CC1 channel is configured as input, IC1 is mapped on TI2
		11: CC1 channel is configured as input, IC1 is mapped to TRC. This mode is only active when
		the internal trigger input is selected by TIMx_SMCTRL.TSEL.
		Note: CC1SEL is writable only when the channel is off $(TIMx_CCEN.CC1EN = 0)$.

9.4.9 Capture/compare enable registers (TIMx_CCEN)

Offset address: 0x20

Reserved CC2P CC2EN Reserved CC1P CC1EN	15									6	5	4	3	2	1	0

Bit field	Name	Description
15:6	Reserved	Reserved, the reset value must be maintained.
5	CC2P	Capture/Compare 2 output polarity
		See TIMx_CCEN.CC1P description.
4	CC2EN	Capture/Compare 2 output enable
		See TIMx_CCEN.CC1EN description.

Bit field	Name	Description
3:2	Reserved	Reserved, the reset value must be maintained
1	CC1P	Capture/Compare 1 output polarity
		When the corresponding channel of CC1 is in output mode:
		0: OC1 active high
		1: OC1 active low
		When the corresponding channel of CC1 is in input mode:
		At this time, this bit is used to select whether IC1 or the inverse signal of IC1 is used as the trigger
		or capture signal.
		0: non-inverted: Capture action occurs when IC1 generates a rising edge. When used as external
		trigger, IC1 is non-inverted.
		1: inverted: Capture action occurs when IC1 generates a falling edge. When used as external
		trigger, IC1 is inverted.
		Note: If $TIMx_BKDT.LCKCFG = 3 \text{ or } 2$, these bits cannot be modified.
0	CC1EN	Capture/Compare 1 output enable
		When the corresponding channel of CC1 is in output mode:
		0: Disable - Disable output OC1 signal.
		1: Enable - Enable output OC1 signal.
		When the corresponding channel of CC1 is in input mode:
		At this time, this bit is used to disable/enable the capture function.
		0: Disable capture
		1: Enable capture

CCxEN	N OCx output status							
0	Disable output (OCx=0)							
1	OCx = OCxREF + polarity							

Note: The state of external I/O pins connected to standard OCx channels depends on the OCx channel state and GPIO and AFIO registers.

9.4.10 Counters (TIMx_CNT)

Offset address: 0x24

15										0
	1 1	1 1	1		1	1	1	1 1	1	
				CNT[15:0]					
1	1 1							1 1		
				rv	v					

Bit field	Name	Description
15:0	CNT[15:0]	Counter value

9.4.11 Prescaler (TIMx_PSC)

Offset address: 0x28

Reset value: 0x0000

15												0
		1					1		1	1	1 1	
					PSC[15:0]						
		I	1	 					1	L	I I	

Bit field	Name	Description
15:0	PSC[15:0]	Prescaler value
		Counter clock $f_{CK_CNT} = f_{CK_PSC}/(PSC [15:0] +1)$.
		Each time an update event occurs, the PSC value is loaded into the active prescaler register.

9.4.12 Auto-reload register (TIMx_AR)

Offset address: 0x2C

Reset values: 0xFFFF

15										0
1	1 1			1	1				1	
				AR[15:0]					
	1 1			1	1		1	1	1	
				r	w					

Bit field	Name	Description
15:0	AR[15:0]	Auto-reload value
		These bits define the value that will be loaded into the actual auto-reload register.
		See Section 8.3.1 for more details.
		When the TIMx_AR.AR [15:0] value is null, the counter does not work.

9.4.13 Capture/compare register 1 (TIMx_CCDAT1)

Offset address: 0x34

15													0
	1	1	1	1	1	1		1		1			
							CCDAT	[1][15:0]					
						I				1	1		
							rw	v/r					

Bit field	Name	Description
15:0	CCDAT1[15:0]	Capture/Compare 1 value
		CC1 channel is configured as output:
		CCDAT1 contains the value to be compared to the counter TIMx_CNT, signaling on the OC1
		output.

Bit field	Name	Description
		If the preload feature is not selected in TIMx_CCMOD1.OC1PEN bit, the written value is
		immediately transferred to the active register. Otherwise, this preloaded value is transferred to the
		active register only when an update event occurs.
		CC1 channel is configured as input:
		CCDAT1 contains the counter value transferred by the last input capture 1 event (IC1).
		When configured as input mode, register CCDAT1 is only readable.
		When configured as output mode, register CCDAT1 is readable and writable.

9.4.14 Capture/compare register 2 (TIMx_CCDAT2)

Offset address: 0x38

Reset value: 0x0000

15													0	
				1	1	1			1	1	1	1		
	CCDAT2[15:0]													

rw/r

Bit field	Name	Description
15:0	CCDAT2[15:0]	Capture/Compare 2 values
		CC2 channel is configured as output:
		CCDAT2 contains the value to be compared to the counter TIMx_CNT, signaling on the OC2
		output.
		If the preload feature is not selected in TIMx_CCMOD1.OC2PEN bit, the written value is
		immediately transferred to the active register. Otherwise, this preloaded value is transferred to the
		active register only when an update event occurs.
		CC2 channel is configured as input:
		CCDAT2 contains the counter value transferred by the last input capture 2 event (IC2).
		When configured as input mode, register CCDAT2 is only readable.
		When configured as output mode, register CCDAT2 is readable and writable.

10 Basic timers (TIM6)

10.1 Basic timers introduction

The basic timer contains a 16-bit counter, it also provides the ability to wake the system from a low-power mode.

10.2 Main features of Basic timers

- 16-bit auto-reload up-counting counters.
- 16-bit programmable prescaler. (The frequency division factor can be configured with any value between 1 and 65536)

- The events that generate the interrupt are as follows:
 - Update event
- Support STOP mode wake-up: When the clock source is configured as LSI, STOP mode can be awakened by updating interrupts (connected to EXTI19).

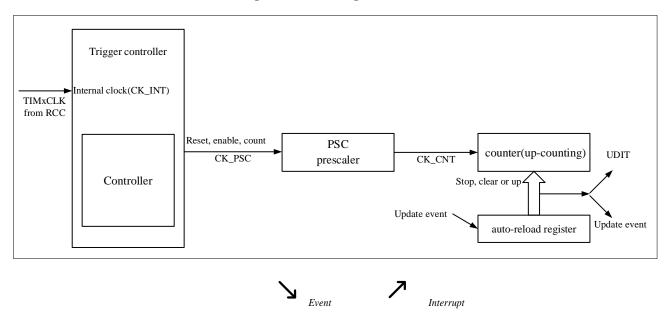

Figure 10-1 Block diagram of TIM6

10.3 Basic timers description

10.3.1 Time-base unit

The time-base unit mainly includes: prescaler, counter and auto-reload. When the time base unit is working, the software can read and write the corresponding registers (TIMx_PSC, TIMx_CNT and TIMx_AR) at any time.

Note: When the clock source is configured for LSI, TIMx_CNT does not support writes.

Depending on the setting of the auto-reload preload enable bit (TIMx_CTRL1.ARPEN), the value of the preload register is transferred to the shadow register immediately or at each update event UEV. when TIMx_CTRL1.UPDIS=0, an update event is generated when the counter reaches the overflow condition or the software settings TIMx_EVTGEN.UDGN bit. The counter CK_CNT is valid only when the TIMx_CTRL1.CNTEN bit is set.

10.3.1.1 Prescaler description

The TIMx_PSC register consists of a 16-bit counter that can be used to divide the counter clock frequency by any factor between 1 and 65536. It can be changed on the fly as it is buffered. The prescaler value is only taken into account at the next update event.

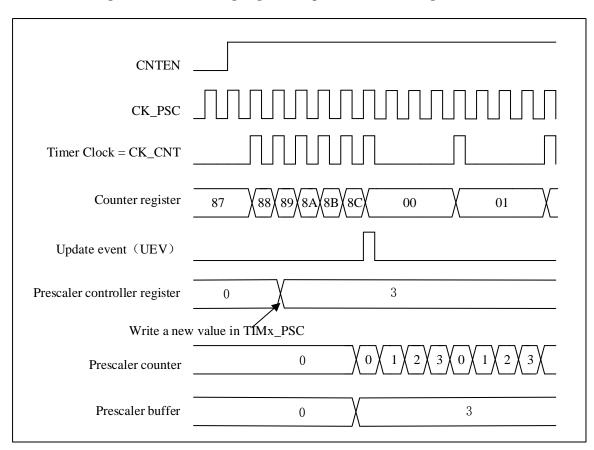

Figure 10-2 Counter timing diagram with prescaler division change from 1 to 4

10.3.2 **Counter mode**

10.3.2.1 Up-counting mode

In up-counting mode, the counter will count from 0 to the value of the register TIMx_AR, then it resets to 0. And a counter overflow event is generated.

If the TIMx_CTRL1.UPRS bit (select update request) and the TIMx_EVTGEN.UDGN bit are set, an update event (UEV) will generate, and TIMx_STS.UDITF will not be set by hardware. Therefore, no update interrupts requests are generated. This setting is used in scenarios where you want to clear the counter but do not want to generate an update interrupt.

Depending on the update request source is configured in the TIMx_CTRL1.UPRS, When an update event occurs, all registers are updated and the TIMx_STS.UDITF is set:

- Update auto-reload shadow registers with preload value(TIMx_AR), when TIMx_CTRL1.ARPEN = 1.
- The prescaler shadow register is reloaded with the preload value(TIMx_PSC)

To avoid updating the shadow registers when new values are written to the preload registers, you can disable the update by setting TIMx_CTRL1.UPDIS=1.

When an update event occurs, the counter will still be cleared and the prescaler counter will also be set to 0 (but the prescaler value will remain unchanged).

The figure below shows some examples of the counter behavior and the update flags for different division factors in the up-counting mode.

10.3.3 Clock selection

■ The internal clock of timers: CK_INT

10.3.3.1 Internal clock source (CK_INT)

It is provided that the TIMx_CTRL1.CNTEN bit is written as' 1 ' by software, the clock source of the prescaler is provided by the internal clock CK_INT.

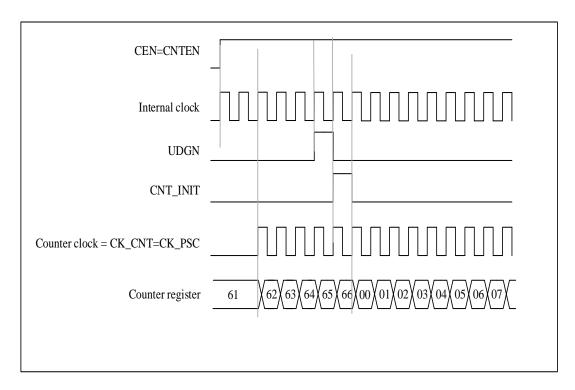

Figure 10-5 Control circuit in normal mode, internal clock divided by 1

10.3.4 **Debug mode**

When the microcontroller is in debug mode (the Cortex-M0 core halted), depending on the DBG_CTRL.TIM6STP configuration in the PWR module, the TIM6 counter can either continue to work normally or stop. For more details, see section 3.4.9.

10.4 TIMx register(x=6)

For abbreviations used in registers, see section 1.1

These peripheral registers can be operated as half word (16-bits) or word (32-bits).

Table 10-1 Register overview

10.4.2 Control Register 1 (TIMx_CTRL1)

Offset address: 0x00

Reset value: 0x0000

Bit field	Name	Description
15:8	Reserved	Reserved, the reset value must be maintained
7	ARPEN	ARPEN: Auto-reload preload enable

217 / 319

Bit field	Name	Description
		0: Shadow register disable for TIMx_AR register
		1: Shadow register enable for TIMx_AR register
6:4	Reserved	Reserved, the reset value must be maintained
3	ONEPM	One-pulse mode
		0: Disable one-pulse mode, the counter counts are not affected when an update event occurs.
		1: Enable one-pulse mode, the counter stops counting when the next update event occurs
		(clearing TIMx_CTRL1.CNTEN bit)
2	UPRS	Update request source
		This bit is used to select the UEV event sources by software.
		0: If update interrupt request is enabled, any of the following events will generate an update
		interrupt request:
		Counter overflow
		The TIMx_EVTGEN.UDGN bit is set
		1: If update interrupt request is enabled, only counter overflow will generate update interrupt
		request
1	UPDIS	Update disable
		This bit is used to enable/disable the Update event (UEV) events generation by software.
		0: Enable UEV. UEV will be generated if one of following condition been fulfilled:
		Counter overflow
		The TIMx_EVTGEN.UDGN bit is set
		Shadow registers will update with preload value.
		1: UEV disabled. No update event is generated, and the shadow registers (AR, PSC) keep their
		values. If the TIMx_EVTGEN.UDGN bit is set, the counter and prescaler are reinitialized.
0	CNTEN	Counter Enable
		0: Disable counter
		1: Enable counter

10.4.3 Interrupt Enable Registers (TIMx_DINTEN)

Offset address: 0x0C

Reset value: 0x0000

15										1	0
	1	1	1	1	1		1	1	1	1	
					Reserved						UIEN
I					 	I I	 1	I			
											rw

Bit field	Name	Description
15:1	Reserved	Reserved, the reset value must be maintained
0	UIEN	Update interrupt enable
		0: Disable update interrupt
		1: Enables update interrupt

10.4.4 Status Registers (TIMx_STS)

Offset address: 0x10

Reset value: 0x0000

15								1	0
				Reserved					UDITF
									rc_w0

Bit field	Name	Description
15:1	Reserved	Reserved, the reset value must be maintained
0	UDITF	Update interrupt flag
		This bit is set by hardware when an update event occurs under the following conditions:
		-When TIMx_CTRL1.UPDIS = 0, and counter value overflow.
		-When TIMx_CTRL1.UPDIS = 0 and TIMx_CTRL1.UPRS = 0, and set the
		TIMx_EVTGEN.UDGN bit by software to reinitialize the CNT.
		This bit is cleared by software.
		0: No update event occurred
		1: Update interrupt occurred

10.4.5 Event Generation registers (TIMx_EVTGEN)

Offset address: 0x14

Reset values: 0 x0000

	15										1	0
		1	1	1		1	Reserved					UDGN
L												w

Bit field	Name	Description
15:1	Reserved	Reserved, the reset value must be maintained.
0	UDGN	Update generation
		Software can set this bit to update configuration register value and hardware will clear it
		automatically.
		0: No effect.
		1: Timer counter will restart and all shadow register will be updated. It will restart prescaler
		counter also.

10.4.6 Counters (TIMx_CNT)

Offset address: 0x24

Reset value: 0x0000

15											0
	1		1		1				1	1	
						CNT[15:0]				
	I			1	1				1	1	

rw

Bit field	Name	Description
15:0	CNT[15:0]	Counter value
		Note: When the clock source is configured for LSI, TIMx_CNT does not support writes

10.4.7 Prescaler (TIMx_PSC)

Offset address: 0x28

Reset value: 0x0000

15													0
	1	1	1	1		DOOL	15.01	1			1		-
						PSC[[15:0]						
	1	1	1	1	1		1		1	1	1	1	1

rw

Bit field	Name	Description
15:0	PSC[15:0]	Prescaler value
		PSC register value will be updated to prescaler register at update event. Counter clock frequency
		is input clock frequency divide PSC + 1.

10.4.8 Automatic reload register (TIMx_AR)

Offset address: 0x2C

Reset values: 0xFFFF

15											0
(· ·	1			A.D.[15:0]	1		I	I	
				1	AK	15:0]		i.	,		
					r	w					

Bit field	Name	Description
15:0	AR[15:0]	Auto-reload value
		These bits define the value that will be loaded into the actual auto-reload register.
		See 10.3.1 for more details.
		When the TIMx_AR.AR [15:0] value is null, the counter does not work.

11 Independent watchdog (IWDG)

11.1 IWDG introduction

The N32G003 has built-in independent watchdog (IWDG) timers to solve the problems caused by software errors. Watchdog timer is very flexible to use, which improves the security of the system and the accuracy of timing control.

Independent Watchdog (IWDG) is driving by Low-speed internal clock (LSI clock) running at 32 KHz, which will still running event dead loop or MCU stuck is happening. This can provide higher safety level, timing accuracy and flexibility of watchdog. It can reset and resolve system malfunctions due to software failure. The IWDG is best suited for applications that require the watchdog to run as a totally independent process outside the main application, but have lower timing accuracy constraints.

When the power control register PWR_CTRL.IWDGRSTEN bit is '1' and the IWDG counter reaches 0, a system reset will be generated (if this bit is '0', the IWDG will count but not reset). IWDG reset can also be used for low power wake up.

Note: This chapter is based on the system default value PWR_CTRL.IWDGRSTEN = 1.

11.2 IWDG main features

- A 12-bit decrement counter that runs independently
- The initial count value of the decrementing counter can be configured, and the pre-frequency can be configured
- After the watchdog is enabled, a system reset occurs when the decrement counter reaches 0x000
- Reset enable is configurable
- Support software/hardware startup
- Can choose to stop counting or work normally in debug mode
- Support low power consumption mode: you can choose to work or freeze in stop mode

11.3 IWDG function description

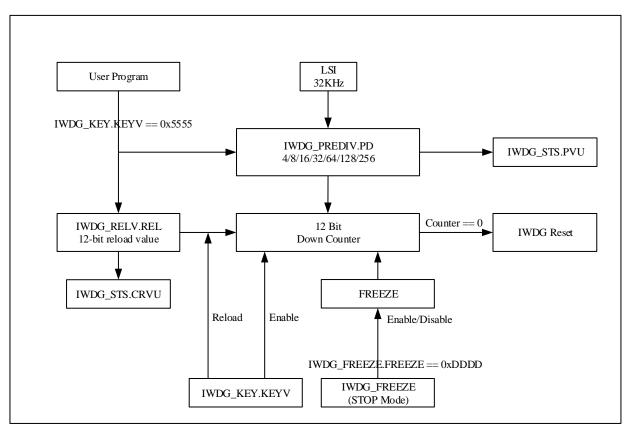

Figure 11-1 Functional block diagram of the independent watchdog module

To enable IWDG, we need to write 0xCCCC to IWDG_KEY.KEYV[15:0] bits. Counter starts counting down from reset value (0xFFF). When counter count to 0x000, it generates a reset signal (IWDG_RESET) to MCU. Write 0xDDDD to IWDG_FREEZE enable the IWDG freeze function, the freeze function can be configured to make the IWDG counter work or stop in STOP mode. Other than that, as long as 0xAAAA (reload request) is write to IWDG_KEY.KEYV[15:0] bits before reset, the counter value is set to the reload value in the IWDG_RELV.REL[11:0] bits and prevents the watchdog from resetting the entire device.

If the "hardware watchdog timer" function is enabled through the option byte, the watchdog will automatically start running after the system is powered on and will generate a system reset, unless the software reloads the counter before it reaches '0'.

11.3.1 Register access protection

IWDG_PREDIV and IWDG_RELV register are write protected. To modify the value of those two register, user needs to write 0x5555 to IWDG_KEY.KEYV[15:0] bits. Writing other value enables write protections again. IWDG_STS.PVU indicates whether the pre-scaler value update is on going. IWDG_STS.CRVU indicates whether the IWDG is updating the reload value. The hardware sets the IWDG_STS.PVU bit and/or IWDG_STS.CRVU bit when the pre-scaler value and/or reload value is updating. After the pre-scaler value and/or reload value update is complete, the hardware clears the IWDG_STS.PVU bit and/or IWDG_STS.CRVU bit.

The reload operation (IWDG_KEY.KEYV[15:0] configured with value of 0xAAAA) will also cause the registers to

222 / 319

become write protected again.

11.3.2 **Debug mode**

In debug mode (Cortex-M0 core stops), IWDG counter will either continue to work normally or stops, depending on DBG_CTRL.IWDG_STOP bit in PWR module. If this bit is set to '1', the counter stops. The counter works normally when the bit is '0'. For details, see 3.3.2 Peripheral Debugging Support.

11.3.3 Low power consumption

The working clock of IWDG can be controlled by configuring the IWDG_FREEZE register to ensure the IWDG is suspended in the stop mode. See the chapter IWDG Freeze register for details 11.5.6.

11.4 User Interface

IWDG module user interface contains 5 registers: Key Register (IWDG_KEY), Pre-scale Register (IWDG_PREDIV), Reload Register (IWDG_RELV), Freeze Register(IWDG_FREEZE) and Status Register (IWDG_STS).

11.4.1 Operate Flow

When IWDG is enable from reset from software (write 0xAAAA to IWDG_KEY.KEYV[15:0] bits) or hardware (clear FLASH_OB.WDG_SW bit). It starts counting down from 0xFFF. Down counting gap is determined by prescale LSI clock. Once the counter is reloaded, each new round will start from the value in IWDG_RELV.REL[11:0] instead of 0xFFF.

When program is running normally, software needs to feed IWDG before counter reaches 0x000 and start a new round of down counting. When counter reach 0x000, this indicates program malfunction. IWDG generates reset signal under this circumstance.

If user wants to configure IWDG pre-scale and reload value register, it needs to write 0x5555 to IWDG_KEY.KEYV[15:0] first. Then confirm IWDG_STS.CRVU bit and IWDG_STS.PVU bit. IWDG_STS.CRVU bit indicates reload value update is ongoing, IWDG_STS.PVU indicates Pre-scale divider ratio is updating. Only when those two bit are 0 then user can update corresponding value. When update is on-going, hardware sets corresponding bit to 1. At this time, reading IWDG_PREDIV.PD[2:0] or IWDG_RELV.REL[11:0] is invalid since data needs sync to LSI clock domain. The value read from IWDG_PREDIV.PD[2:0] or IWDG_RELV.REL[11:0] will be valid after hardware clears the IWDG_STS.PVU bit or IWDG_STS.CRVU bit.

If the application uses more than one reload value or pre-scaler value, it must wait until the IWDG_STS.CRVU bit is reset before changing the reload value, the same as changing the pre-scaler value. However, after updating the pre-scale and/or the reload value, it is not necessary to wait until IWDG_STS.CRVU bit and/or IWDG_STS.PVU bit are reset before continuing code execution (even in case of low-power mode entry, the write operation is taken into account and will complete).

Pre-scale register and reload register controls the time that generates reset, as shown in Table 13 1.

Table 11-1 IWDG overtime time at 32kHz

Prescaler divider	IWDG_PREDIV [2:0]	Min timeout (ms) (IWDG_PELV11:0]=0)	Max timeout (ms) (IWDG_PELV[11:0]=0xFFF)
/4	000	0.125	512
/8	001	0.25	1024
/16	010	0.5	2048
/32	011	1	4096
/64	100	2	8192
/128	101	4	16384
/256	11x	8	32768

11.4.2 IWDG configuration flow

Software flow:

- 1. Write 0x5555 to IWDG_KEY.KEYV[15:0] bits to enable write access of IWDG_PREDIV and IWDG_RELV registers.
- 2. Check IWDG_STS.PVU bit and IWDG_STS.CRVU bit, if they are 0, continue next step.
- 3. Configure IWDG_PREDIV.PD[2:0] bits to select pre-scale value.
- 4. Configure IWDG_RELV.REL[11:0] bits reload value.
- 5. Writing 0xAAAA to IWDG_KEY.KEYV[15:0] bits to upload counter with reload value.
- 6. Configure the IWDG_FREEZE register
- 7. Write 0xCCCC to IWDG_KEY.KEYV[15:0] bits to start the watchdog

If you need to modify the prescaler value and reload value, repeat steps 1 to 5; if you don't need to reconfigure, just perform step 5 to feed the dog at regular intervals.

11.5 IWDG registers

11.5.2 IWDG Key register (IWDG_KEY)

Address offset: 0x00

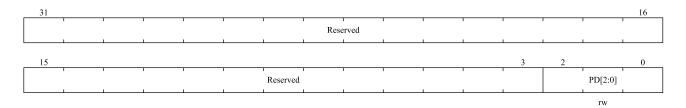

Reset value: 0x0000 0000

31					 			 					16
						Rese	erved						
	1	1	1	1					1		1	1	
15		-								-		•	0
						KEYV	[15:0]						
						rc_	w0						

Bit Field	Name	Description
31:16	Reserved	Reserved, the reset value must be maintained.
15:0	KEYV[15:0]	Key value register: only certain value will serve particular function.
		0xCCCC: Start watch dog counter, does not have any effect if hardware watchdog is
		enable, (if hardware watchdog is selected, it is not limited by this command word)
		0xAAAA: Reload counter with REL value in IWDG_RELV register to prevent reset.
		0x5555: Disable write protection of IWDG_PREDIV and IWDG_RELV register

11.5.3 IWDG Pre-Scaler register (IWDG_PREDIV)

Address offset: 0x04

Bit Field	Name	Description
31:3	Reserved	Reserved, the reset value must be maintained.
2:0	PD[2:0]	Pre-frequency division factor
		With write access protection when IWDG_KEY.KEYV[15:0] is not 0x5555. The
		IWDG_STS.PVU bit must be 0 otherwise PD [2:0] value cannot be changed. Divide number
		is as follow:
		000: Prescaler divider =4
		001: Prescaler divider =8

	010: Prescaler divider =16
	011: Prescaler divider =32
	100: Prescaler divider =64
	101: Prescaler divider =128
	11x: Prescaler divider =256
	Note: Reading this register will return the pre-divided value from the VDD voltage domain.
	If a write operation is in progress, the read-back value may be invalid. Therefore, the read
	value is valid only when the IWDG_STS.PVU bit is '0'.

11.5.4 IWDG Reload register (IWDG_RELV)

Address offset: 0x08

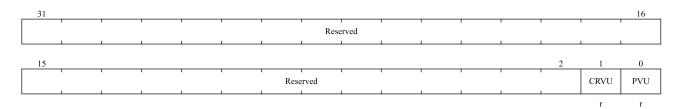

Reset value: 0x0000 0FFF

Bit Field	Name	Description
31:12	Reserved	Reserved, the reset value must be maintained.
11:0	REL[11:0]	Watchdog counter reload value.
		With write protection. Defines the reload value of the watchdog counter, which is loaded to
		the counter every time 0xAAAA is written to IWDG_KEY.KEYV[15:0] bits. The counter
		then starts to count down from this value. The watchdog timeout period can be calculated
		from this reloading value and the clock pre-scaler value, refer to Table 11-1.
		This register can only be modified when the IWDG_STS.CRVU bit is '0'.
		Note: Reading this register will return the reload value from the VDD voltage domain. If a
		write operation is in progress, the read-back value may be invalid. Therefore, the read value
		is valid only when the IWDG_STS.CRVU bit is '0'.

11.5.5 IWDG Status register (IWDG_STS)

Address offset: 0x0C

-

Bit Field	Name	Description
31:2	Reserved	Reserved, the reset value must be maintained.
1	CRVU	Watchdog reload value update
		Reload Value Update: this bit indicates an update of reload value is ongoing. Set by
		hardware and clear by hardware(up to 5 RC cycles of 32kHz) .Software can only try to
		change IWDG_RELV.REL[11:0] value when IWDG_KEY.KEYV[15:0] bits' value is
		0x5555 and this bit is 0.
0	PVU	Watchdog prescaler value update
		Pre-scaler Value Update: this bit indicates an update of pre-scaler value is ongoing. Set by
		hardware and clear by hardware(up to 5 RC cycles of 32kHz). Software can only try to
		change IWDG_PREDIV.PD[2:0] value when IWDG_KEY.KEYV[15:0] bits' value is
		0x5555 and this bit is 0.

11.5.6 IWDG Freeze register (IWDG_FREEZE)

Address offset: 0x010

31												16
	1	1	1	1		Rese	rved	1	1			
	1	1	1	1	L I	1	1	1	1	1	1	I]
15												
											1	
		1				 Reserved		1	i	i .	- 1	0 FREEZE

Bit Field	Name	Description
31:1	Reserved	Reserved, the reset value must be maintained.
0	FREEZE	STOP mode freeze function
		1. The initial value of IWDG_FREEZE.FREEZE bit is 0x00;
		2. When writing 0xDDDD to this address, IWDG_FREEZE.FREEZE flips once and
		becomes 1, and controls counter stops after entering STOP mode.
		3. When 0xDDDD is written to the address again, IWDG_FREEZE.FREEZE flips once and
		becomes 0, and controls counter continues to count after entering STOP mode.
		4. And so on
		The current value of IWDG_FREEZE.FREEZE can be determined by reading the freeze
		register firstly, and then the switch freeze operation can be performed.

12 Analog to digital conversion (ADC)

12.1 ADC introduction

The 12-bit ADC is a high-speed analog-to-digital converter using successive approximation. It can measure 10 channel signal source. It has 9 external and 1 internal channel. Each channel of the A/D conversion performed in single, continuous or scan mode. ADC measurements are stored (left-aligned/ right-aligned) in 16-bit data registers. The application can detect that the input voltage is within user-defined high/low thresholds by analog watchdog and the maximum frequency of the input clock to the ADC is 24MHz.

12.2 Main Features

- Supports 1 ADC, supports single-ended inputs, and can measure 9 external and 1 internal sources
- Supports 12-bit resolution with a maximum sampling rate of 1MSPS
- ADC clock source is divided into working clock source and timing clock source
 - ♦ HSI as the ADC_CLK working clock source, up to 24M.
 - HSI as the ADC_1MCLK timing clock source for internal timing functions, the frequency must be configured to 1MHz.
- Supports timer trigger ADC sampling
- Interrupts when conversion ends, and simulated watchdog events occur
- Support 2 conversion modes
 - Single conversion
 - Continuous conversion
- Scan mode supports up to any 5 channels, each channel has an independent result data register buffer
- All channel sampling intervals can be programmed uniformly
- Regular conversion has external triggering options
- ADC power supply requirements: 2.4V to 5.5V
- ADC input range: $0 \le V_{IN} \le V_{DD}$

12.3 ADC function description

Below is a block diagram of an ADC module. Table 12-1 shows the description of ADC pins.

Figure 12-1 Block diagram of ADC

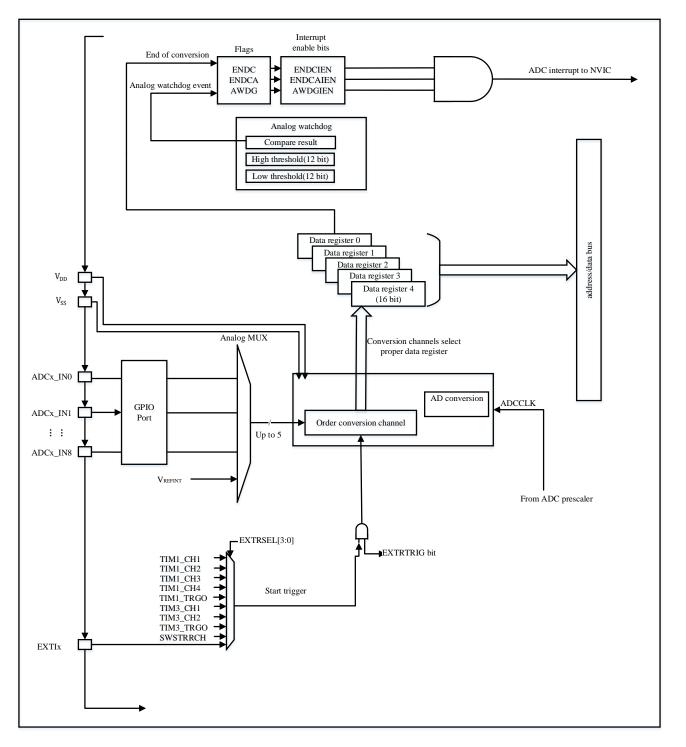

Table 12-1 ADC pins

Name	Signal types	Annotations
V _{DD}	Input, analog power supply	Equivalent to V_{DD} analog power supply and: $2V \leq V_{DD} \leq 5.5~V$
V _{SS}	Input, analog power supply ground	Equivalent to Vss analog power supply ground
ADCx_IN[8:0]	Analog input signal	9 analog external input channels

12.3.1 ADC clock

An ADC requires three clocks, ADC_CLK, HCLK, and ADC_1MCLK.

- HCLK is used for the register access.
- ADC_CLK is the working clock of ADC.
- ADC_1MCLK for internal timing function, configured in RCC, frequency size must be configured to 1M

Note:

1. The ADC_CLK frequency division can be configured as a working clock up to 24MHz. The ADC_CLK frequency division can be 1,2,3,4,6,8,10,12,24,32

12.3.2 ADC switch control

You can proceed to the next step only after the power-up process is complete. You can check if the power-up is complete by polling the ADC_CTRL3.RDY bit.

You can set the ADC_CTRL2.ON bit to turn on the ADC. When the ADC_CTRL2.ON bit is set for the first time, it wakes up the ADC from the power-off state. After a power-on delay of ADC (t_{STAB}), and the conversion begins when the ADC_CTRL2.ON bit is set again.

The conversion can be stopped by clearing the ADC_CTRL2.ON bit and placing the ADC in power-off mode. In this mode, the ADC consumes almost no power (just a few μ A). Power-down can be checked by polling the ADC_CTRL3.PDRDY bit.

When the ADC is disabled, the default mode is power-down.

12.3.3 Channel selection

Each channel can be configured as a regular sequence. A series of conversions in any order on any number of channels. For example, the conversion can be completed in the following order: channel 3, channel 8, channel 2, channel 1, channel 0.

Regular sequence consists of multiple conversions, up to a maximum of 5. The ADC_DATx.SEQx[3:0] registers bits specify the regular channels and their conversion. The ADC_CTRL2.LEN[2:0] bits specified the regular channel sequence length.

Note: During conversion, changes to the ADC_DATx.SEQx[3:0] are prohibited; the ADC_DATx.SEQx[3:0] registers can only be changed when the ADC is idle.

12.3.4 Internal channel

The VREFINT is connected with channel ADC_IN9.

Internal channels can be converted by regular channels.

12.3.5 Single conversion mode

The ADC can enter the single conversion mode by configuring ADC_CTRL2.CTU to 0. In this mode, external triggering or setting ADC_CTRL2.ON=1 can start the ADC to start conversion, and the ADC only performs one conversion.

After the conversion starts, when a regular channel conversion is completed, the regular channel conversion end flag(ADC_STS.ENDC) will be set to 1. If the regular channel conversion end interrupt enable (ADC_CTRL1.ENDCIEN) bit is set to 1, an interrupt will be generated at this time, and the converted data will be stored in the ADC_DATx.DAT[15:0] register.

After single conversion, the ADC stops.

12.3.6 Continuous conversion mode

The ADC can enter the continuous conversion mode by configuring ADC_CTRL2. CTU to 1. In this mode, external triggering or setting ADC_CTRL2.ON to 1 can start the ADC to start conversion, and the ADC will continuously convert the selected channel.

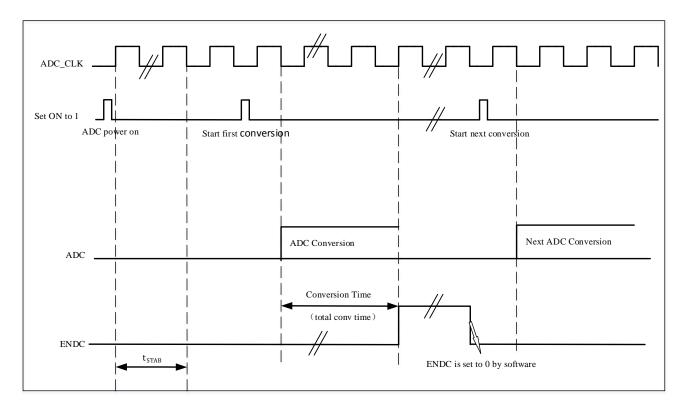

After the conversion starts, when a regular channel conversion is completed, the regular channel end of conversion flag bit (ADC_STS.ENDC) will be set to 1. If the regular channel conversion end interrupt enable bit (ADC_CTRL1.ENDCIEN) is set to 1 at this time, an interrupt will be generated. The converted data will be stored in the ADC_DATx.DAT[15:0] register.

12.3.7 **Timing diagram**

When ADC_CTRL2.ON is set to 1 for the first time, the ADC is powered on. After the ADC is powered on, the ADC needs a certain time(tSTAB) to ensure its stability. After the ADC is stabilized, ADC_CTRL2.ON is set to 1. At this time, set ADC_CTRL2.ON to 1 again through software. To start the conversion and after 24 cycles, the end of conversion flag bit will be set to 1 after the conversion is completed.

12.3.8 Analog watchdog

The analog watchdog can be enabled on the regular channel by setting ADC_CTRL1.AWDGERCH to 1. The high threshold of the analog watchdog can be set by configuring ADC_WDGHIGH.HTH, and the low threshold of the analog watchdog can be set by configuring ADC_WDGLOW.LTH. The threshold of the analog watchdog has nothing to do with the way of data alignment, because the comparison of the ADC's conversion value with the threshold is done before the alignment. When the value of ADC analog conversion is higher than the high threshold of the analog watchdog or lower than the low threshold of the analog watchdog, the analog watchdog flag (ADC_STS.AWDG) will be set to 1, if ADC_CTRL1.AWDGIEN has been configured to 1, an interrupt will be generated at this time. The analog watchdog can be controlled for one or more channels by configuring ADC_CTRL1.AWDSGSGLEN and ADC_CTRL1.AWDGCH[3:0].

Table 12-2 Analog watchdog	channel selection
----------------------------	-------------------

Channel	ADC_CTRL1 regi	ister control bit
Channel	AWDGSGLEN	AWDGERCH
All regular channels	0	1
Single regular channel	1	1

12.3.9 **Scan mode**

By configuring ADC_CTRL1.SCAMD to 1, the scan mode can be turned on, and by configuring the registers ADC_DATx.SEQx[3:0], the conversion sequence can be selected, and the ADC will scan and convert all the selected

channels, each sequence can select any channel for conversion. After the conversion is started, the channels will be converted sequentially one by one, supporting up to 5 conversion sequences. If ADC_CTRL2.CTU is 1 at this time, the conversion will be restarted from the first channel of the conversion sequence after the conversion of all selected channels is completed.

12.4 Data aligned

There are two alignment methods for data storage after conversion: left-aligned and right-aligned. The alignment can be set by the ADC_CTRL2.ALIG bit. ADC_CTRL2.ALIG = 0 is right-aligned, $ADC_CTRL2.ALIG = 1$ is left-aligned, as shown in following tables.

0	0	0	0	D11	D10	D9	D8	D7	D6	D5	D4	D3	D2	D1	D0
---	---	---	---	-----	-----	----	----	----	----	----	----	----	----	----	----

Table 12-4 Left-align data

D11	D10	D9	D8	D7	D6	D5	D4	D3	D2	D1	D0	0	0	0	0

12.5 Programmable channel sampling time

Specify the number of sampling cycles of ADC in ADC_SAMPT.SAMP[4:0], and then the ADC samples the input voltage in the specified sampling cycle. For different channels, Sampling intervals can be programmed uniformly. The total conversion time is calculated as follows:

 $T_{CONV} =$ Sampling time + 12 cycles

Example:

ADCCLK=24MHz, the sampling time is 12 cycles and resolution is 12bit, the total conversion time is "12 + 12" ADCCLK Cycles, that is:

 $T_{CONV} = 12 + 12 = 24$ cycle = 1µs

Note: All ADC channels share a channel sample time configuration.

12.6 Externally triggered conversion

For the regular sequence, software sets the ADC_CTRL2.EXTRTRIG bit to 1, then the regular channel can use the rising edge of the external event to trigger the start conversion, and then the software sets the ADC_CTRL2.EXTRSEL[3:0] bits to select the external trigger source of the regular sequence. The external trigger source selection is shown in the table below. If you select EXTI line as the external trigger source, you can set the AFIO_CFG.EXTI_ETRR[4:0] bits to implement; if you select SWSTRRCH as the external trigger source, you can start the regular channel conversion by setting ADC_CTRL2.SWSTRRCH to 1.

EXTRSEL[3:0]	Trigger source	Туре
0000	TIM1_CC1 event	Internal signal from the on-chip timer

EXTRSEL[3:0]	Trigger source	Туре
0001	TIM1_CC2 event	
0010	TIM1_CC3 event	
0011	TIM1_CC4 event	
0100	TIM1_TRGO event	
0101	TIM3_TRGO event	
0110	TIM3_CC1 event	
0111	TIM3_CC2 event	
1000	EXTI line event	External pin/internal signal from on-chip timer
1001	SWSTRRCH	Software control bit

12.7 ADC interrupt

ADC interrupts can be from an end of regular sequence conversion, an analog watchdog event when input voltage exceeds the threshold, any end of regular channel conversion. These interrupts have independent interrupt enable bits.

There is a status flags in the ADC_STS register: regular sequence channel conversion started (STR). But there are no interrupts associated with this flag in the ADC.

Table 12-6 ADC interrupt

Interrupt event	Event flags	Enable control bit
Regular sequence conversion is complete	ENDC	ENDCIEN
Analog watchdog status bit is set	AWDG	AWDGIEN
Any regular channel interruption is enabled	ENDCA	ENDCAIEN

12.8.2 ADC status register (ADC_STS)

Address offset: 0x00

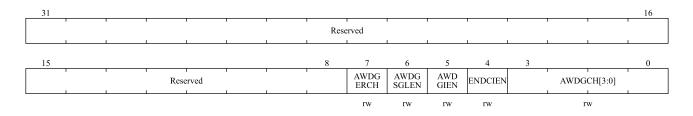

Bit Field	Name	Description
31:4	Reserved	Reserved, the reset value must be maintained.
3	ENDCA	Any channel End of conversion Flag
		This bit is set by hardware at the end of regular channel conversion and cleared by software.
		0: The conversion is not complete;
		1: The conversion is complete.
2	STR	Regular channel start flag
		This bit is set by hardware at the start of regular channel conversion and cleared by software.
		0: Regular channel conversion has not started.
		1: Regular channel conversion has started.
1	ENDC	End of conversion
		This bit is set by hardware at the end of channel group conversion and cleared by software
		0: the conversion is not complete.
		1: The conversion is complete.

Bit Field	Name	Description
0	AWDG	Analog watchdog flag
		This bit is set by hardware and cleared by software when converted voltage values are outside the
		range defined by the ADC_WDGHIGH.HTH and ADC_WDGLOW.LTH registers
		0: No simulated watchdog event occurs;
		1: The simulated watchdog event occurs.

12.8.3 ADC control register 1 (ADC_CTRL1)

Address offset: 0x04

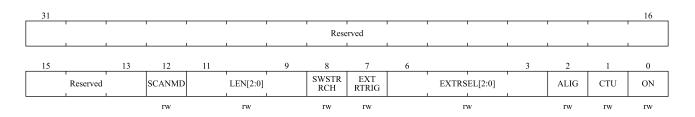

Bit Field	Name	Description
31:8	Reserved	Reserved, the reset value must be maintained.
7	AWDGERCH	Analog watchdog enable on regular channels
		This bit is set and cleared by the software.
		0: Disables analog watchdog on regular channel.
		1: Use analog watchdog on regular channels.
6	AWDGSGLEN	Enable the watchdog on a single channel in scan mode
		This bit is set and cleared by software to enable or disable analog watchdog functions on
		channels specified by ADC_CTRL1.AWDGCH[3:0]
		0: Use watchdog on all channels.
		1: Use watchdog on single channel.
5	AWDGIEN	Analog watchdog interrupt enable
		This bit is set and cleared by software to disallow or allow interrupt generated by simulated
		watchdog.In scan mode, if the watchdog detects an out-of-range value, the scan is aborted only
		when that bit is set.
		0: Disable analog watchdog interruption.
		1: Enable analog watchdog interruption.
4	ENDCIEN	Interrupt enable for any channels
		This bit is set and cleared by the software to disallow or allow interrupts to occur after the
		regular channel conversion ends.
		0: Disable ENDC interruption.
		1: Enable ENDC interruption.
3:0	AWDGCH[3:0]	Analog watchdog channel select bits
		These bits are set and cleared by software. They select the input channel to be guarded by

Bit Field	Name	Description
		the analog watchdog.
		0000: ADC analog Channel0
		0001: ADC analog Channel1
		1001: ADC analog Channel9
		Reserved all other values.

12.8.4 ADC control register 2 (ADC_CTRL2)

Address offset: 0x08

Bit Field	Name	Description
31:13	Reserved	Reserved, the reset value must be maintained.
12	SCANMD	Scan mode
		This bit is set and cleared by the software to enable or disable scan mode. In scan mode, the
		conversion is made by ADC_DATx.ADC_SEQx[3:0] register.
		0: Disable scan mode.
		1: Enable scan mode.
		Note: If the ADC_CTRL1.ENDCIEN bits are set separately, ADC_STS.ENDC interrupts occur
		only after the last channel has been converted.
11:9	LEN[2:0]	Channel sequence length
		These bits are written by software to define the total number of conversions in the
		channel conversion sequence.
		000: 1 conversion
		001: 2 conversions
		010: 3 conversions
		011: 4 conversions
		100: 5 conversions
8	SWSTRRCH	Start conversion of channels
		This bit is set by software to start conversion and cleared by hardware as soon as
		conversion starts. It starts a conversion of a group of channels if SWSTRRCH is
		selected as trigger event by the ADC_CTRL2.EXTRSEL[3:0] bits.
		0: Reset state
		1: Starts conversion of channels

Bit Field	Name	Description
7	EXTRTRIG	External trigger conversion mode for channels
		This bit is set and cleared by software to enable or disable external triggering events that can
		initiate channel group conversion.
		0: Start conversion without external events;
		1: Use an external event to start the conversion.
6:3	EXTRSEL[3:0]	External event select for regular sequence
		These bits select external events to start the regular sequence conversion
		The triggering configuration of ADC is as follows:
		0000: Timer 1 CC1 event
		0001: Timer 1 CC2 event
		0010: Timer 1 CC3 event
		0011: Timer 1 CC4 event
		0100: Timer 1 TRGO event
		0101: Timer 3 TRGO event
		0110: Timer 3 CC1 event
		0111: Timer 3 CC2 event
		1000: EXTI line
		1001: SWSTRRCH
2	ALIG	Data alignment
		This bit is set and cleared by the software.
		0: Right-aligned;
		1: Left-align.
1	CTU	Continuous conversion
		This bit is set and cleared by the software. If this bit is set, the conversion continues until the bit
		is cleared.
		0: single conversion mode.
		1: Continuous conversion mode.
0	ON	A/D Converter ON/OFF
		This bit is set and cleared by the software. When the bit is' 0 ', writing '1' will wake the ADC
		from power-off mode.
		When the bit is' 1 ', writing '1' starts the conversion. The application should note that there is a
		delay t between the time the converter is powered on and the time the conversion begins t_{STAB} ,
		see Figure 12-2.
		0: close ADC conversion and enter power off mode;
		1: Start ADC and start conversion.
		Note: If there are other bits changed in this register along with ON, the conversion will not be
		triggered. This is to prevent the wrong conversion from being triggered.

12.8.5 ADC control register 3 (ADC_CTRL3)

Address offset: 0x0C

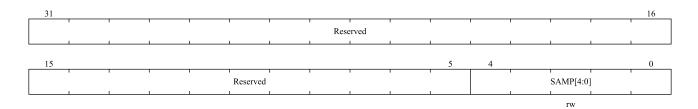

31															16
			1	1	1	1	Rese	rved		1	1	1	1

Bit Field	Name	Description
31:6	Reserved	Reserved, the reset value must be maintained.
5	ENDCAIEN	Interrupt enable for any channels
		This bit is set and cleared by the software to enable/disable channel conversion to end the interrupt
		0: ADC_STS.ENDCA interrupt is disabled
		1: ADC_STS.ENDCA interrupt is enabled
4	PDRDY	ADC power down ready
		0: ADC is powered on
		1: ADC is powered down
3	RDY	ADC Ready
		0: Not ready
		1: Get ready
2	VREFRDY	VREFINT_READY
		ADC internal input buffer ready status, software must check this status bit before measuring
		VREFINT
		0: VREFINT not ready
		1: VREFINT is ready
1	VREFEN	VREFINT Enable
		ADC internal input buffer is enabled, software must enable this bit before measuring VREFINT
		0: Disable VREFINT measurement
		1: Enable VREFINT measurement
0	Reserved	Reserved, the reset value must be maintained.

12.8.6 ADC sampling time register (ADC_ SAMPT)

Address offset: 0x10

Bit Field	Name	Description
31:5	Reserved	Reserved, the reset value must be maintained.
4:0	SAMP[4:0]	Channel sample time selection
		These bits are written by software to select the sample time for channel.
		During sample cycles channel selection bits must remain unchanged.
		00000: reserved
		00001: 8 cycles(only set for working clock of 20MHz, the frequency of HSI is 40MHz)
		00010: 12 cycles
		00011: 14 cycles
		00100: 20 cycles
		00101: 26 cycles
		00110: 30 cycles
		00111: 42 cycles
		01000: 56 cycles
		01001: 72 cycles
		01010: 88 cycles
		01011: 120 cycles
		01100: 182 cycles
		01101: 240 cycles
		01110: 380 cycles
		01111: 760 cycles
		10000: 1520 cycles
		10001: 3040 cycles

12.8.7 ADC watchdog high threshold register (ADC_WDGHIGH)

Address offset: 0x14

Reset value: 0x00000FFF

31											•			 16

Bit Field	Name	Description
31:20	Reserved	Reserved, the reset value must be maintained.
19:16	SEQx[3:0]	Conversion channel of selecting proper data register
		0000: channel 0
		1001: channel 9
		Others: reserved
15:0	DATx[15:0]	Regular data for conversions
		These bits are read-only and contain the conversion results of the regular channel. The data is left-
		aligned or right-aligned.

13 Comparator (COMP)

The COMP module is used to compare the analog voltages of two inputs and output high/low levels based on the comparison results. When the input voltage of "INP" is higher than the input voltage of "INM", the comparator output is high; when the input voltage of "INP" is lower than the input voltage of "INM", the comparator output is low.

13.1 COMP system connection block diagram

The COMP module supports an independent comparator, which is connected to the APB bus.

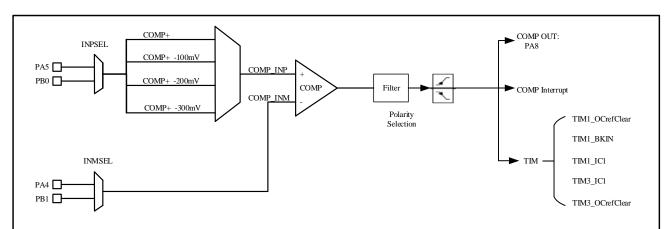

Figure 13-1 Comparator system connection diagram

13.2 COMP features

- Operate votage 2.4~5.5V
- A comparator with substraction, support positive port input voltage(500mV~VDD-200mV) minus a reference voltage(300/200/100/0mV)
- Support filter clock
- Output polarity can be configured high and low
- The hysteresis configuration can be configured with none, low, medium, or high
- The comparison result can be output to the I/O port or trigger timer, which is used to capture events, OCREF_CLR events, brake events, and generate interrupts
- Input channel can select I/O ports
- Can be equipped with read-only or read-write, it needs to be reset to unlock when locked
- Support blanking, configurable blanking source to generate blanking
- Filter window size can be configured
- Filter threshold size can be configured
- The sampling frequency for filtering can be configured

13.3 COMP configuration process

Complete configuration items are as follows. If the default configuration is used, skip the corresponding configuration items.

- 1. Configurable hysteresis level COMP_CTRL.HYST[1:0].
- 2. Configure the output polarity COMP_CTRL.POL.
- 3. Configuration input selection, comparator positive COMP_CTRL.INPSEL, negative COMP_CTRL.INMSEL.
- 4. Configure the subtraction value at the positive input COMP_CTRL.CMPVOS[1:0].
- 5. Configure output selection COMP_CTRL.OUTTRG[2:0].
- 6. Configure the blanking source COMP_CTRL.BLKING.
- 7. Configure the filter sampling window COMP_FILC.SAMPW[4:0].
- 8. Configure the threshold COMP_FILC.THRESH[4:0](threshold should be greater than COMP_FILC.SAMPW[4:0]/2).
- 9. Configure the filter sampling frequency (for timer applications, sampling frequency should be greater than 5MHz).
- 10. Enable COMP_FILC.FILEN filter.
- 11. Enable COMP_CTRL.EN on the comparator.

Note: For the above steps, the filter should be enabled first and then the comparator should be enabled. The comparator should be enabled after the filtering (if enabled) is configured and enabled. In addition, when the comparator control register is locked, the LOCK can be cancelled only through reset.

13.4 COMP working mode

13.4.1 Independent comparator

One comparator can be configured independently to complete the comparator function. The output of the comparator can be output to I/O ports. The comparator supports different remapping ports. and the output of the comparator can be selected and connected to the corresponding port through configuration.

Comparator output, support trigger events, for example, it can be configured as timer 1 brake function.

Note: Refer to the comparator interconnection for specific configuration

13.5 Comparator interconnection

For interconnection of comparator output ports, please refer to the AFIO remapping chapter, Remap IO multiplexing function in GPIOx_AFL/AFH.

COMP_OUT can be mapped to PA8, The comparator INP pins have the following configuration:

INPSEL	COMP
0	PB0
1	PA5

The comparator INM pins have the following configuration

INMSEL	COMP
0	PB1
1	PA4

The signals of TRIG output by the comparator have the following interconnections

TRIG	COMP
000	NC
001	TIM1_BKIN
010	TIM1_IC1
011	TIM1_OCrefclear
100	TIM3_IC1
101	TIM3_OCrefclear
Other	

13.6 Interrupt

COMP supports interrupt response. There are two types of interrupts.

- The polarity of COMP_CTRL.POL is not reversed and the interrupt is enabled. When INPSEL > INMSEL, the comparator interrupt will be generated when COMP_CTRL.OUT is set to 1 by hardware.
- The polarity of COMP_CTRL.POL is reversed and the interrupt is enabled. When INPSEL < INMSEL, the comparator interrupt will be generated when COMP_CTRL.OUT is set to 1 by hardware.

13.7 COMP registers

13.7.1 **COMP registers**

14 Inter-integrated circuit bus(I²C)

14.1 Introduction

I2C(Inter-Integrated Circuit) bus is a widely used bus structure, it has only two bidirectional lines, namely data bus SDA and clock bus SCL. All devices compatible with I2C bus can communicate directly with each other through I2C bus with these two lines.

I2C interface connects microcontroller and serial I2C bus, and can be used for communication between MCU and external I2C devices. It supports standard speed mode and fast mode, it supports CRC calculation and verification, it also provides multi-master function to control all I2C bus specific timing, protocol, arbitration.

14.2 Main features

- Same interface can have both master function and slave function
- Parallel-bus to I²C protocol converter
- Supports 7-bit/10-bit address mode and broadcast addressing
- As I²C master, it can generate clock, start and stop signal
- As I²C slave, it supports programmable address detection, stop bit detection function
- Support standard speed mode(up to 100 kHz), fast mode(up to 400 kHz) and fast plus mode(up to 1MHz)
- Support interrupt vector: byte transfer successfully interrupt and error event interrupt
- Optional clock extending function
- Optional PEC (Packet Error Check) generation and verification
- Programmable analog and digital noise filters

14.3 Function description

I2C interface is connected to I2C bus through data pin (SDA) and clock pin (SCL) to communicate with external devices. It can be connected to standard (up to 100kHz) or fast (up to 400kHz,1MHz) I2C bus. I2C module converts data from serial to parallel when receiving, and converts data from parallel to serial when sending. It support interrupt mode, users can enable or disable interrupt according to their needs.

14.3.1 SDA and SCL line control

I2C module has two interface lines: serial data line (SDA) and serial clock line (SCL). Devices connected to the bus and transmit information to each other through these two wires. SDA and SCL are two-way wires, it should connected to a current source or the positive of the power supply with a pull-up resistor. When the bus is idle, both lines are high level. The output of device which is connected to the bus must have open drain or open collector to provide wired-AND functionality. The data on I2C bus can reach 100 kbit/s in standard mode and 1000 kbit/s in fast mode. Since devices of different processors may be connected to the I2C bus, the levels of logic '0' and logic '1' are not fixed

and depend on the actual level of VDD.

If the clock extending is allowed, the SCL line is pulled low which can be avoided the overload error during receiving and the under load error during transmission.

For example, when in the transmission mode, if the transmit data register is empty and the byte transfer finish bit is set (I2C_STS1.TXDATE = 1, I2C_STS1.BSF = 1), the I2C interface keeps the clock line low before transmission to wait for the software to read STS1 and write the data into the data register (both buffer and shift register are empty); when In the receive mode, if the data register is not empty and the byte transfer finish bit is set (I2C_STS1.RXDATNE = 1, I2C_STS1.BSF = 1), the I2C interface keeps the clock line low after receiving the data byte, waiting for the software to read STS1, and then read the data register(buffer and shift register are full).

If clock extending is disable in slave mode, if the receive data register is not empty (I2C_STS1.RXDATNE = 1) in the receive mode, and the data has not been read before receiving the next byte, an overrun error will issue and the last word byte will be discarded. In transmit mode, if the transmit data register is empty (I2C_STS1.TXDATE = 1), no new data is written into the data register before the next byte must be sent, an underrun error will issue. The same byte will be send repeatedly. In this case, duplicate write conflicts are not controlled.

14.3.2 Software communication process

The data transmission of I2C device is divided into master and slave. Master is the device responsible for initializing the transmission of data on the bus and generating clock signal. At this time, any addressed device is a slave. Whether the I2C device is a master or a slave, it can send or receive data. Therefore, the I2C interface supports four operation modes:

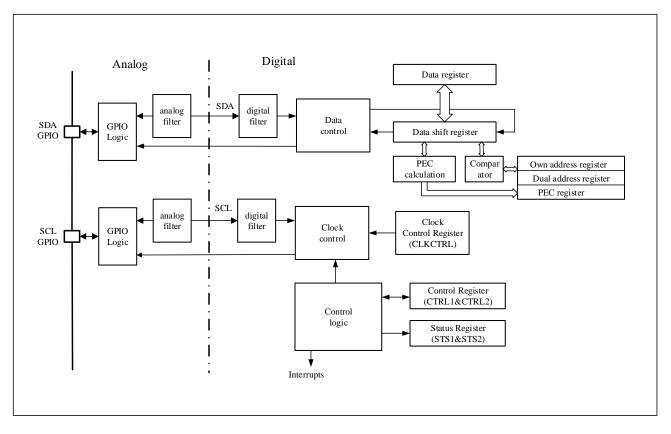

- Slave transmitter mode
- Slave receiver mode
- Master transmitter mode
- Master receiver mode

After system reset, I2C works in slave mode by default. The I2C interface is configured by software to send a start bit on the bus, and then the interface automatically switches from the slave mode to the master mode. When arbitration is lost or a stop signal is generated, the interface will switched to the slave mode from the master mode.

The functional block diagram of I²C interface is shown in the figure below.

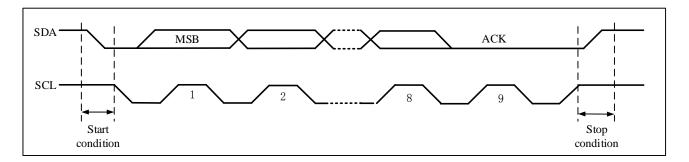

14.3.2.1 Start and stop conditions

All data transfers always start with the start bit and end with the stop bit. The start and stop conditions are generated by software in the master mode. Start bit is a level conversion from high to low on SDA line when SCL is high. Stop bit is a level conversion from low to high on SDA line when SCL is high. as shown in the figure below.

Figure 14-2 I2C bus protocol

14.3.2.2 Clock synchronization and Arbitration

The I2C module supports multi-master arbitration, which means two masters can start transferring data on an idle bus at the same time. So some mechanisms are needed to decide which master takes control of the bus, which is usually done through Clock Synchronization and Arbitration.

I2C module has two key features:

SDA and SCL are drain open circuit structures, and the signal "wire-and" logic is realized through an external

pull-up resistor.

SDA and SCL pins will also detect the level on the pin while outputting the signal to check whether the output is consistent with the previous output.

This provides the hardware basis for "Clock Synchronization" and "Bus Arbitration".

The I2C device on the bus is to output logic 0 by "grounding the line". Based on the characteristics of the I2C bus, if one device sends logic 0 and the other sends logic 1, then the line sees only logic 0, so there is no possibility of level conflicts on the line.

The physical connection of the bus allows the master to read data while writing data to the bus. In this way, when two masters are competing for the bus, the one that sends logic 0 does not know the occurrence of the competition. Only the one that sends logic 1 will find the conflict (when writing a logic 1, but read 0) and exit the competition.

Clock synchronization

Multiple masters can generate clocks on an idle bus at the same time. The high-to-low switching of the SCL line causes the devices to begin counting their low-level periods, and once the device's clock goes low, it keeps the SCL line in this state until the high-level of the clock is reached. However, if another clock is still in the low period, the low-to-high switch of this clock will not change the state of the SCL line. Therefore, the SCL line is kept low by the device with the longest low-level period. A device with a short low-level period will enter a high-level wait state.

When all related devices have counted their low-level periods, the clock line is released and goes high-level, after which there is no difference in the state of the device clock and SCL lines, and all devices will begin counting their high-level periods, the device that completes the high-level period first will pull the SCL line low again.

In this way, the low-level period of the generated synchronous SCL clock is determined by the device with the longest low-level clock period, and the high-level period is determined by the device with the shortest high-level clock period.

Arbitration

Arbitration, like synchronization, is to resolve bus control conflicts in the case of multiple masters. The arbitration process has nothing to do with the slave. When the two masters both produce a valid start bit when the bus is idle, in this case, it is necessary to decide which master will complete the data transmission. This is the process of arbitration.

Each master controller does not have the priority level of controlling the bus, which is all determined by arbitration. The bus control is determined and carried out bit by bit. They follow the principle of "low level first", that is, whoever sends the low level first will control the bus. During the arbitration of each bit, when SCL is high, each host checks whether its own SDA level is the same as that sent by itself. In theory, if the content transmitted by two hosts is exactly the same, then they can successfully transmit without errors. If a host sends a high level but detects that the SDA line is low, it considers that it has lost arbitration and shuts down its SDA output driver, while the other host continues to complete its own transmission.

14.3.2.3 I2C data communication flow

Each I2C device is identified by a unique address. According to the device function, they can be either a transmitter or a receiver.

The I2C host is responsible for generating the start bit and the end bit in order to start and end a transmission. And is responsible for generating the SCL clock.

The I2C module supports 7-bit and 10-bit addresses, and the user can configure the address of the I2C slave through

software. After the I2C slave detects the start bit on the I2C bus, it starts to receive the address from the bus, and compares the received address with its own address. Once the two addresses are matched, the I2C slave will send an acknowledgement (ACK) and respond to subsequent commands on the bus: send or receive the requested data. In addition, if the software opens a broadcast call, the I2C slave always sends a confirmation response to a broadcast address (0x00).

Data and address are transmitted in 8-bit width, with the most significant bit first. The 1 or 2 bytes following the start condition is the address (1 byte in 7-bit mode, 2 bytes in 10-bit mode). The address is only sent in master mode. During the 9th clock period after 8 clocks of a byte transmission, the receiver must send back an acknowledge bit (ACK) to the transmitter, as shown in the Figure 14-2 I2C bus protocol.

Software can enable or disable acknowledgement (ACK), and can set the I2C interface address (7-bit, 10-bit address or broadcast call address).

14.3.2.4 I2C slave transmission mode

In slave mode, the transmission reception flag bit (I2C_STS2.TRF) indicates whether it is currently in receiver mode or transmission mode. When sending data to I2C bus in transmission mode, the software should follow the following steps:

- 1. First, enable I2C peripheral clock and configure the related register in I2C_CTRL2, ensuring the correct I2C timing. After these two steps are completed, I2C runs in slave mode, waiting for receiving start bit and address.
- 2. I2C slave receives a start bit first, and then receives a matching 7-bit or 10-bit address. I2C hardware will set the I2C_STS1.ADDRF(received address and matched its own address). The software should monitor this bit regularly or have an interrupt to monitor this bit. After this bit is set, the software reads I2C_STS1 register and then read I2C_STS2 register to clear the I2C_STS1.ADDRF bit. If the address is in 10 bit format, the I2C master should then generate a START and send an address header to the I2C bus. After detecting START and the following address header, the slave will continue to set I2C_STS1.ADDRF bit. The software continues to read I2C_STS1 register and read I2C_STS2 register to clear the I2C_STS1.ADDRF bit a second time.
- 3. I2C enters the data sending state, and now shift register and data register I2C_DAT are all empty, so the hardware will set the I2C_STS1.TXDATE(send data empty). At this time, the software can write the first byte data to I2C_DAT register, however, because the byte of the I2C_DAT register is immediately moved into the internal shift register, the I2C_STS1.TXDATE bit is not cleared to zero. When the shift register is not empty, I2C starts to send data to I2C bus.
- 4. During the sending of the first byte, the software writes the second byte to I2C_DAT, neither the I2C_DAT register nor the shift register is empty. The I2C_STS1.TXDATE bit is cleared to 0.
- 5. After the first byte is sent, I2C_STS1.TXDATE is set again, and the software writes the third byte to I2C_DAT, the same time, the I2C_STS1.TXDATE bit is cleared.After that, as long as there is still data to be sent and I2C_STS1.TXDATE is set to 1, the software can write a byte to I2C_DAT register.
- 6. During the sending of the second last byte, the software writes the last data to the I2C_DAT register to clear the I2C_STS1.TXDATE flag bit, and then the I2C_STS1.TXDATE status is no longer concerned. The I2C_STS1.TXDATE bit is set after the second last byte is sent until the stop end bit is detected.
- 7. According to the I2C protocol, the I2C master will not send a ACK to the last byte received. Therefore, after the last byte is sent, the I2C_STS1.ACKFAIL bit (acknowledge fail) of the I2C slave will be set to notify the software

of the end of sending. The software writes 0 to the I2C_STS1.ACKFAIL bit to clear this bit.

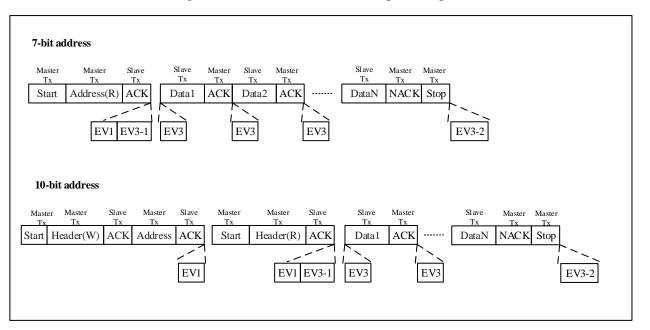

Figure 14-3 Slave transmitter transfer sequence diagram

Instructions:

- 1. EV1: I2C_STS1.ADDRF = 1, read STS1 and then STS2 to clear the event.
- 2. EV3-1: I2C_STS1.TXDATE=1, shift register is empty, data register is empty, write DAT.
- 3. EV3: I2C_STS1.TXDATE=1, shift register is not empty, data register is empty, write DAT will clear the event.
- 4. EV3-2: I2C_STS1.ACKFAIL=1, ACKFAIL bit of STS1 register write "0" to clear the event.

Note:

- *a) EV1 and EV3_1 event prolongs the low SCL time until the end of the corresponding software sequence.*
- *b)* The software sequence of EV3 must be completed before the end of the current byte transfer.

14.3.2.5 I2C slave receiving mode

When receiving data in slave mode, the software should operate as follows:

- 1. First, enable I2C peripheral clock and configure the related register in I2C_CTRL2 ensuring the correct I2C timing. After these two steps are completed, I2C runs in slave mode, waiting for receiving start bit and address.
- 2. After receiving the START condition and the matched 7-bit or 10-bit address, I2C hardware will set I2C_STS1.ADDRF bit(the address received and matched with its own address) to 1. This bit should be detected by software polling or interrupt. After it is found that it is set, the software clears the I2C_STS1.ADDRF bit by reading I2C_STS1 register first and then I2C_STS2 register. Once the I2C_STS1.ADDRF bit is cleared, The I2C slave starts to receive data from the I2C bus.
- 3. When the first byte is received, the I2C_STS1.RXDATNE bit (the received data is not empty) is set to 1 by hardware. If the I2C_CTRL2.EVTINTEN and I2C_CTRL2.BUFINTEN bits are set, an interrupt is generated. The software should check this bit by polling or interrupt. Once it is found that it is set, the software can read the first byte of I2C_DAT register, and then the I2C_STS1.RXDATNE bit is cleared to 0. Note that if the

I2C_CTRL1.ACKEN bit is set, after receiving a byte, the slave should generate a response pulse.

- 4. At any time, as long as the I2C_STS1.RXDATNE bit is set to 1, the software can read a byte from the I2C_DAT register. When the last byte is received, I2C_STS1.RXDATNE is set to 1 and the software reads the last byte.
- 5. When the slave detects the STOP bit on I2C bus, set I2C_STS1.STOPF to 1, and if the I2C_CTRL2.EVTINTEN bit is set, an interrupt will be generated. The software clears the I2C_STS1.STOPF bit by reading the I2C_STS1 register before writing the I2C_CTRL1 register (see EV4 in the following figure).

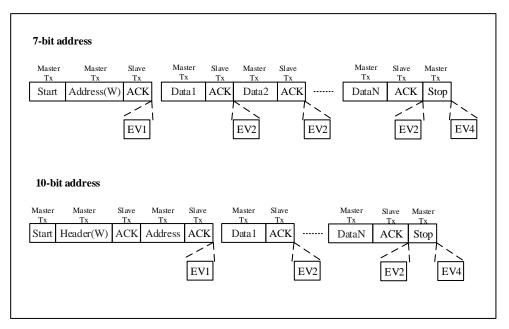

Figure 14-4 Slave receiver transfer sequence diagram

Instructions:

- 1. $EV1: I2C_STS1.ADDRF = 1$, read STS1 and then STS2 to clear the event.
- 2. EV2: I2C_STS1.RXDATNE =1, reading DAT will clear this event.
- 3. EV4: I2C_STS1.STOPF=1, reading STS1 and then writing the CTRL1 register will clear this event.

Note:

- a) EV1 event prolongs the time when SCL is low until the end of the corresponding software sequence.
- *b)* The software sequence of EV2 must be completed before the end of the current byte transmission.

14.3.2.6 I2C master transmission mode

In the master mode, the I2C interface starts data transmission and generates a clock signal. Serial data transmission always starts with a start condition and ends with a stop condition. When the START condition is generated on the bus through the start bit, the device enters the master mode.

When sending data to I2C bus in master mode, the software should operate as follows:

1. First, enable the I2C peripheral clock, and configure the related registers in I2C_CTRL2 to ensure the correct I2C timing. When these two steps are completed, I2C runs in the slave mode by default, waiting for receiving the start bit and address.

- 2. When BUSY=0, I2C_CTRL1.STARTGEN bit set to 1, and the I2C interface will generate a start condition and switch to the master mode (I2C_STS2.MSMODE=1).
- 3. Once the start condition is issued, I2C hardware will set I2C_STS1.STARTBF bit(START bit flag)and then enters the master mode. If the I2C_CTRL2.EVTINTEN bit is set, an interrupt will be generated. Then the software reads the I2C_STS1 register and then writes a 7-bit address bit or a 10-bit address bit with an address header to the I2C_DAT register to clear the I2C_STS1.STARTBF bit. After the I2C_STS1.STARTBF bit is cleared to 0, I2C starts sending addresses or address headers to I2C bus.

In 10-bit address mode, sending a header sequence will generate the following events:

- ◆ I2C_STS1.ADDR10F bit is set by hardware, and if I2C_CTRL2.EVTINTEN bit is set, an interrupt is generated. Then the master reads the STS1 register, and then writes the second address byte into the DAT register.
- ◆ I2C_STS1.ADDRF bit is set by hardware, and if I2C_CTRL2.EVTINTEN bit is set, an interrupt is generated. Then the master reads the STS1 register, followed by the STS2 register.

Note: In the transmitter mode, the master device first sends the header byte (11110xx0) and then sends the lower 8 bits of the slave address. (where xx represents the highest 2 bits of the 10-bit address).

In the 7-bit address mode, only one address byte needs to be sent out. Once the address byte is sent out:

◆ I2C_STS1.ADDRF bit is set by hardware, and if I2C_CTRL2.EVTINTEN bit is set, an interrupt is generated. Then the master device waits for reading the STS1 register once, followed by reading the STS2 register.

Note: in the transmitter mode, when the master sends the slave address, set the lowest bit to "0".

Note: In 7-bit address mode, don't set the slave address to 0xF0 to prevent the I2C_STS1.ADDR10F bit from being set by hardware.

- 4. After the 7-bit or 10-bit address bit is sent, the I2C hardware sets the I2C_STS1.ADDRF bit (address has been sent) to 1, if the I2C_CTRL2.EVTINTEN bit is set, an interrupt is generated, and the software is cleared by reading the I2C_STS1 register and then the I2C_STS2 register I2C_STS1.ADDRF.
- 5. I2C enters the data transmission state. Because the shift register and the data register (I2C_DAT) are empty, the hardware sets the I2C_STS1.TXDATE bit (transmission data empty) to 1, and then the software writes the first byte of data to the I2C_DAT register, but because the byte written into the I2C_DAT register is immediately moved into the internal shift register, the I2C_STS1.TXDATE bit will not be cleared at this time. Once the shift register is not empty, I2C starts sending data to the bus.
- 6. During the transmission of the first byte, the software writes the second byte to I2C_DAT, and I2C_STS1.TXDATE is cleared at this time. At any time, as long as there is data waiting to be sent and the I2C_STS1.TXDATE bit is set to 1, the software can write a byte to the I2C_DAT register.
- 7. In the process of sending the penultimate byte, the software writes the last byte of data to I2C_DAT to clear the I2C_STS1.TXDATE flag bit. After that, there is no need to care about the status of the I2C_STS1.TXDATE bit. The I2C_STS1.TXDATE bit will be set after the penultimate byte is sent, and will be cleared when the stop bit (STOP) is sent.
- 8. After the last byte is sent, because the shift register and the I2C_DAT register are empty at this time, the I2C host sets the I2C_STS1.BSF bit (byte transmission end), and the I2C interface will keep SCL low before clearing the I2C_STS1.BSF bit. After reading I2C_STS1, writing to the I2C_DAT register will clear the I2C_STS1.BSF

bit. The software sets the I2C_CTRL1.STOPGEN bit at this time to generate a stop condition, and then the I2C interface will automatically return to the slave mode (I2C_STS2.MSMODE bit is cleared).

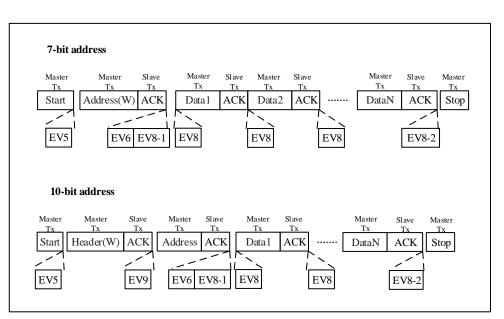

Figure 14-5 Master transmitter transfer sequence diagram

Instructions:

- 1. EV5: I2C_STS1.STARTBF = 1, reading STS1 and writing the address to the DAT register will clear the event.
- 2. EV6: I2C_STS1.ADDRF = 1, read STS1 and then STS2 to clear the event.
- 3. EV8_1: I2C_STS1.TXDATE = 1, shift register is empty, data register is empty, write DAT register.
- 4. EV8: I2C_STS1.TXDATE = 1, shift register is not empty, data register is empty, write to DAT register will clear the event.
- 5. EV8_2: I2C_STS1.TXDATE = 1, I2C_STS1.BSF = 1, request to set stop bit. These two events are cleared by the hardware when a stop condition is generated.
- 6. EV9: I2C_STS1.ADDR10F = 1, read STS1 and then write to DAT register to clear the event.

Note:

- *a) EV5, EV6, EV9, EV8_1 and EV8_2 event prolonged the low SCL time until the end of the corresponding software sequence.*
- *b)* The software sequence of EV8 must be completed before the end of the current byte transfer.
- c) When I2C_STS1.TXDATE or I2C_STS1.BSF bit is set, stop condition should be arranged when EV8_2 occurs.

14.3.2.7 I2C master receiving mode

Support BYTENUM byte control mode, in the master receive mode, after configuring the number of bytes received, the hardware automatically ends the communication, without software intervention to configure NACK and send START/STOP conditions, of course, you can also use the ordinary master receive mode.

In master mode, software receiving data from I2C bus should follow the following steps:

1. First, enable the I2C peripheral clock and configure the related registers in I2C_CTRL2, in order to ensure that the correct I2C timing is output. After enabling and configuring, I2C runs in slave mode by default, waiting to receive the start bit and address.

Note: If you need to enable master receive byte control, you need to additionally enable I2C_BYTENUM.BYTENUMEN after enabling the I2C peripheral clock in this step, and configure the number of bytes to received through I2C_BYTENUM.BYTENUM, and I2C_BYTENUM.RXFSEL selects the master to send START or STOP conditions after the receive is finish.

- 2. When BUSY=0, set the I2C_CTRL.STARTGEN bit, and the I2C interface will generate a start condition and switch to the master mode (I2C_STS2.MSMODE bit is set to 1).
- 3. Once the start condition is issued, the I2C hardware sets I2C_STS1.STARTBF(start bit flag) and enters the host mode. If the I2C_CTRL2.EVTINTEN bit is set to 1, an interrupt will be generated. Then the software reads the I2C_STS1 register and then writes a 7-bits address or a 10-bits address with an address header to the I2C_DAT register, in order to clear the I2C_STS1.STARTBF bit. After the I2C_STS1.STARTBF bit is cleared to 0, I2C begins to send the address or address header to the I2C bus.

In 10-bits address mode, sending a header sequence will generate the following events:

- The I2C_STS1.ADDR10F bit is set to 1 by hardware, and if the I2C_CTRL2.EVTINTEN bit is set to 1, an interrupt will be generated. Then the master device reads the STS1 register, and then writes the second byte of address into the DAT register.
- The I2C_STS1.ADDRF bit is set to 1 by hardware, and if the I2C_CTRL2.EVTINTEN bit is set to 1, an interrupt will be generated. Then the master device reads the STS1 register and the STS2 register in sequence.

Note: In the receiver mode, the master device sends the header byte (11110xx0) firstly, then sends the lower 8 bits of the slave address, and then resends a start condition followed by the header byte (11110xx1) (where xx represents the highest 2 digits of the 10-bits address).

In the 7-bits address mode, only one address byte needs to be sent, once the address byte is sent:

• The I2C_STS1.ADDRF bit is set to 1 by hardware, and if the I2C_CTRL2.EVTINTEN bit is set to 1, an interrupt will be generated. Then the master device waits to read the STS1 register once, and then reads the STS2 register.

Note: In the receiving mode, the master device sets the lowest bit as '1' when sending the slave address.

Note: In 7-bit address mode, don't set the slave address to 0xF0 to prevent the I2C_STS1.ADDR10F bit from being set by hardware.

- 4. After the 7-bits or 10-bits address is sent, the I2C hardware sets the I2C_STS1.ADDRF bit (address has been sent) to 1. If the I2C_CTRL2.EVTINTEN bit is set to 1, an interrupt will be generated. The software clears the I2C_STS1.ADDRF bit by reading the I2C_STS1 register and the I2C_STS2 register in sequence. If in the 10-bit address mode, software should set the I2C_CTRL1.STARTGEN bit again to regenerate a START. After the START is generated, the I2C_STS1.STARTBF bit will be set. The software should clear the I2C_STS1.STARTBF bit by reading I2C_STS1 firstly and then writing the address header to I2C_DAT, and then the address header is sent to the I2C bus, I2C_STS1.ADDRF is set to 1 again. The software should clear the I2C_STS1.ADDRF bit again by reading I2C_STS1 and I2C_STS2 in sequence.
- 5. After sending the address and clearing the I2C_STS1.ADDRF bit, the I2C interface enters the host receiving mode. In this mode, the I2C interface receives data bytes from the SDA line and sends them to the DAT register through the internal shift register. Once the first byte is received, the hardware will set the

I2C_STS1.RXDATNE bit (not empty flag bit of received data) to 1, and if the I2C_CTRL1.ACKEN bit is set to 1, an acknowledge pulse will be sent. At this time, the software can read the first byte from the I2C_DAT register, and then the I2C_STS1.RXDATNE bit is cleared to 0. After that, as long as I2C_STS1.RXDATNE is set to 1, the software can read a byte from the I2C_DAT register.

6. The master device sends a NACK after receiving the last byte from the slave device. After receiving the NACK, the slave device releases the control of SCL and SDA lines; the master device can send a stop/restart condition. In order to generate a NACK pulse after receiving the last byte, the software should clear the I2C_CTRL1.ACKEN bit immediately after receiving the penultimate byte (N-1). In order to generate a stop/restart condition, the software must set the I2C_CTRL1.STOPGEN bit or I2C_CTRL1.STARTGEN to 1 after reading the penultimate data byte. This process needs to be completed before the last byte is received to ensure that the NACK is sent for the last byte.

Note: If the master receive byte control is enabled earlier, steps 6 and 7 can be ignored, the software only needs to read the bytes according to the receive flag, and the hardware will automatically send NACK and START/STOP conditions after the the receive is finish.

7. After the last byte is received, the I2C_STS1.RXDATNE bit is set to 1, and the software can read the last byte. Since I2C_CTRL1.ACKEN has been cleared to 0 in the previous step, I2C no longer sends ACK for the last byte, and generates a STOP bit after the last byte is sent.

Note: In ordinary master receive mode, the above steps require the number of bytes N>1. If N=1, step 6 should be executed after step 4, and it needs to be completed before the reception of byte is completed.

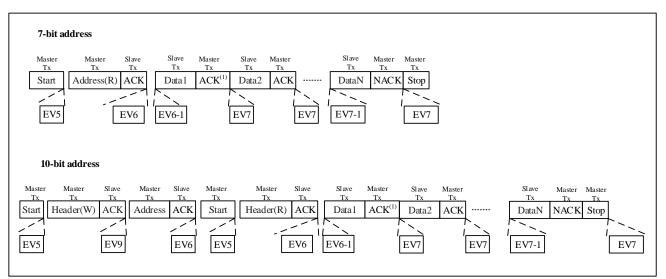

Figure 14-6 Master receiver transfer sequence diagram

Instructions:

- 1. EV5: I2C_STS1.STARTBF=1, reading STS1 and then writing the address into the DAT register will clear this event.
- 2. EV6: I2C_STS1.ADDRF=1, reading STS1 and STS2 in sequence will clear this event. In the 10-bits master receiving mode, the I2C_CTRL1.STARTGEN should be set to 1 after this event.
- 3. EV6_1: There is no corresponding event flag, only suitable for receiving 1 byte. Just after EV6 (that is after clearing I2C_STS1.ADDRF), the generation bits for acknowledge and stop condition should be cleared.
- 4. EV7: I2C_STS1.RXDATNE=1, read the DAT register to clear this event.
- 5. EV7_1: I2C_STS1.RXDATNE =1, read the DAT register to clear this event. Set I2C_CTRL1.ACKEN=0 and

259 / 319

I2C_CTRL1.STOPGEN=1.

6. EV9: I2C_STS1.ADDR10F=1, reading STS1 and then writing to the DAT register will clear this event.

Note:

- a) If a single byte is received, it is NA.
- b) EV5, EV6, and EV9 events extend the low level of SCL until the corresponding software sequence ends.
- c) The EV7 software sequence shall be completed before the end of the current byte transmission.
- *d)* The software sequence of EV6_1 or EV7_1 shall be completed before the ACK pulse of the current transmission byte.

14.3.3 Error conditions description

I2C errors mainly include bus error, acknowledge fail, arbitration loss, overrun\underrun error. These errors may cause communication failure.

14.3.3.1 Acknowledge Failure(ACKFAIL)

The interface have a acknowledge bit is detected that does not match the expectation, it will occurs acknowledge fail error, I2C_STS1.ACKFAIL bit is set. An interrupt occurs, when I2C_CTRL2.ERRINTEN bit is set to 1.

When transmitter receives a NACK, The communication must be reset: Device in slave mode, hardware release the bus; Device in master mode, it must generate a stop condition from software.

14.3.3.2 Bus Error(BUSERR)

when address or data is transmissing,I2C interface receive external stop or start condition, it will happen a bus error, I2C_STS1.BUSERR bit is set. An interrupt occurs, when I2C_CTRL2.ERRINTEN bit is set to 1.

I2C device as master, the hardware does not release bus, as the same time it done not affect the current status of transfer, The current transfer will determined by software whether suspend.

I2C device as slave, when data is discarded in transmission and the bus releases by hardware, it will have two situation: If an error start condition is detected, the slave device considers a restart condition and waits for an address or a stop condition. If an error stop condition is detected, the slave device operates as a normal stop condition and the hardware releases the bus.

14.3.3.3 Arbitration Lost(ARLOST)

The interface have arbitration lost is detected, hardware release the bus, it will occurs arbitration lost error, I2C_STS1.ARLOST bit is set. An interrupt occurs, when I2C_CTRL2.ERRINTEN bit is set to 1.

I2C interface will go to slave mode automatically(I2C_STS2.MSMODE bit is cleared). When the I2C interface lost the arbitration, in the same communication, it can not acknowledge to its slave address as slave, but it can acknowledge when the arbitration winning master retransmits a start signal.

14.3.3.4 Overrun/Underrun Error(OVERRUN)

In slave mode, disable clock extend prone to Overrun/Underrun Error:

When I2C interface is receiving data (I2C_STS1.RXDATNE=1, data have received in register), and I2C_DAT register still have previous byte has not been read, it will occurs an overrun error. In this situation, the last received

260 / 319

data is discarded. And software should clear I2C_STS1.RXDATNE bit, transmitter retransmit last byte.

When I2C interface is sending data (I2C_STS1.TXDATE=1, new data have not sending to register), and I2C_DAT register still empty, it will occurs an underrun error. In this situation, the previous byte in the I2C_DAT register is sending repeatedly. And User make sure that in the event of an underrun error, the receiver discard repeatedly byte, and transmitter should update the I2C_DAT register at the specified time according to the I2C bus standard.

In sending the first byte, I2C_DAT register must be written after I2C_STS1.ADDRF bit is cleared and the before the first SCL rising edge. If cannot make sure do that, the first byte should be discard by receiver.

14.3.4 Packet error check

Setting the I2C_CTRL1.PECEN bit to 1 enables the PEC function. PEC uses CRC-8 algorithm to calculate all information bytes including address and read/write bits.it can improve the reliability of communication. The CRC-8 polynomial uses by the PEC calculator is $C(x) = x^8 + x^2 + x + 1$.

In transmit mode, software sets I2C_CTRL1.PEC transfer bit in the last I2C_STS1.TXDATE event, and then PEC will be transmitted after the last byte. While in receiving mode, software sets I2C_CTRL1.PEC transfer bit after the last I2C_STS1.RXDATNE event, and then receives the PEC byte and compares the received PEC byte to the internally calculated PEC value. If it is not equal to the internally calculated PEC value, the receiver needs to send a NACK. If it is master receiver mode, NACK will be sent after PEC regardless of the calculated result. It should pay attention that I2C_CTRL1.PEC bit has to be set before receiving the ACK pulse for the current byte.

When arbitration is lost, PEC calculation is invalid.

14.3.5 Noise filter

I2C interface standard requires that 50ns burr can be filtered on SCL/SDA. So analog filter and digital filter are added in design. By default, analog filter are enable and can be set I2C_TMRISE.SCLAFENN/SDAAFENN to disable. The analog filter can configure I2C_TMRSE.SCLAFE/SDAAFW to set filter burrs with the width of 5ns, 15ns, 25ns, 35ns. Digital filter can be set I2C_TMRISE.SCLDFW/SDADFW is a non-zeor value to enable. The max width of filter is (SCLDEW[3:0] or SDADFW[3:0])*T_{PCLK}. Enabling the digital filter will increase the hold time of SDA and the increment is (SDADFW[3:0]+1)*T_{PCLK}.

14.4 Interrupt request

All I2C interrupt requests are listed in the following table.

Interrupt function	Interrupt event	Event flag	Set control bit
	Start bit sent (master)	STARTBF	
	Address sent (master) or	ADDRF	
	address matched (slave)	ADDKF	
I2C event interrupt	10-bit header sent (master)	ADDR10F	EVTINTEN
	Received stop (slave)	STOPF	
	Data byte transfer finish	BSF	

Table 14-1 I²C interrupt request

Interrupt function	Interrupt event	Event flag	Set control bit
	Receive buffer is not empty.	RXDATNE	EVTINTEN and BUFINTEN
	Transmit buffer is empty.	TXDATE	EVIINTEN and BUFINTEN
	Bus error	BUSERR	
	Lost arbitration (master)	ARLOST	
I2C error interrupt	Acknowledge fail	ACKFAIL	ERRINTEN
	Overrun/underrun	OVERRUN	
	PEC error	PECERR	

Note:

- 1. STARTBF, ADDRF, ADDR10F, STOPF, BSF, RXDATNE and TXDATE are merged into a interrupt channel through logical OR.
- 2. BUSERR, ARLOST, ACKFAIL, OVERRUN and PECERR are merged into a interrupt channel through logical OR.

14.5 I2C registers

These peripheral registers can be operated by half word (16 bits) or word (32 bits)

14.5.1 I2C register overview

14.5.2 I2C Control register 1 (I2C_CTRL1)

Address offset: 0x00

15	14	13	12	11	10	9	8	7	6	5	4		_	1	0
SW RESET	Rese	erved	PEC	ACK POS	ACKEN	STOP GEN	START GEN	NO EXTEND	GCEN	PECEN		Rese	erved	1	EN
rw			rw	rw	rw	rw	rw	rw	rw	rw					rw

Bit field	Name	Description
		Software reset
		Make sure the I2C bus is idle before resetting this bit.
15	SWRESET	0:I2C not reset;
15	SWRESEI	1:I2C reset.
		Note: This bit can be used when the I2C_STS2.BUSY bit is set to 1 and no stop condition is detected
		on the bus.
14:13	Reserved	Reserved, the reset value must be maintained
		Packet error checking
		It can be set or cleared by software. It will be cleared by hardware when PEC has been transferred,
10	PEC	or detect start or stop condition, or when I2C_CTRL1.EN=0.
12	PEC	0: No PEC transfer
		1: PEC transfer.
		Note: When arbitration is lost, the calculation of PEC is invalid.
		Acknowledge/PEC Position (for data reception)
11	ACKDOS	It can be set or cleared by software. Or when I2C_CTRL1.EN=0, it will be cleared by hardware.
11	ACKPOS	0: I2C_CTRL1.ACKEN bit determines whether to send an ACK to the byte currently being
		received; I2C_CTRL1.PEC bit indicates that the byte in the current shift register is PEC.

Bit field	Name	Description
		1: I2C_CTRL1.ACKEN bit etermines whether to send an ACK to the next received byte;
		I2C_CTRL1.PEC bit indicates that the next byte received in the shift register is PEC.
		Note:
		ACKPOS bit can only be used in 2-byte receiving configuration and must be configured before
		receiving data.
		To NACK second byte, the I2C_CTRL1.ACKEN bit must be cleared after the I2C_STS1.ADDRF bit
		is cleared.
		To detect the PEC of the second byte, the I2C_CTRL1.PEC bit must be set after the ACKPOS bit is
		configured and during the ADDR extend event.
		Acknowledge enable
		It can be set or cleared by software. Or when I2C_CTRL1.EN equals to 0, it will be cleared by
10	ACKEN	hardware.
		0: No acknowledge send;
		1: Send an acknowledge after receiving a byte(matched address or data)
		Stop generation
		It can be set or cleared by software. Or it will be cleared by hardware when a stop condition is
		detected.
		In the master mode:
		0: No stop condition generates;
_		1: Generate a stop condition.
9	STOPGEN	In the slave mode:
		0: No stop condition generates;
		1: Release SCL and SDA lines after the current byte.
		Note: When the STOPGEN, STARTGEN or PEC bit is set, the software should not take any write
		operation to I2C_CTRL1 until this bit is cleared by hardware. Otherwise, the STOPGEN,
		STARTGEN or PEC bits may be set twice.
		Start generation
		It can be set or cleared by software. Or it will be cleared by hardware when the start condition is
8	STARTGEN	transferred or I2C_CTRL1.EN=0.
		0: No start condition generates;
		1: Generate a start conditions.
		Clock extending disable (Slave mode)
		This bit determines whether to pull SCL low as slave when the data is not ready(I2C_STS1.ADDRF
7	NOEXTEND	or I2C_STS1.BSF flag is set) in slave mode, and is cleared by software reset
		0: Enable Clock extending.
		1: Disable Clock extending.
		General call enable
6	GCEN	0: Disable General call. not acknowledge(NACK) the address 00h;
		1: Enable General call. acknowledge(ACK) the address 00h.
		PEC enable
5	PECEN	0: Disable PEC module;
		1: Enable PEC module.

Bit field	Name	Description
4:1	Reserved	Reserved, the reset value must be maintained.
		I2C Peripheral enable
		0: Disable I2C module;
0	EN	1: Enable I2C module
0	EIN	Note: If this bit is cleared when communication is in progress, the I2C module is disabled and
		returns to the idle state after the current communication ends, all bits will be cleared.
		In master mode, this bit must never be cleared until the communication has ended.

14.5.3 I2C Control register 2 (I2C_CTRL2)

Address offset: 0x04

	15			11	10	9	8	7	6	5			0
		, , ,	Reserved		BUFINT EN	EVTINT EN	ERRINT EN	Rese	rved		CLKFR	EQ[5:0]	
_					rw	rw	rw				r	w	

Bit field	Name	Description
15:11	Reserved	Reserved, the reset value must be maintained.
10	BUFINTEN	Buffer interrupt enable
		0: When I2C_STS1.TXDATE=1 or I2C_STS1.RXDATNE=1, any interrupt is not generated.
		1: If I2C_CTRL2.EVTINTEN= 1, When I2C_STS1.TXDATE=1 or I2C_STS1.RXDATNE=
		1, interrupt will be generated.
9	EVTINTEN	Event interrupt enable
		0: Disable event interrupt;
		1: Enable event interrupt
		This interrupt is generated when:
		I2C_STS1.STARTBF = 1 (Master)
		I2C_STS1.ADDR $F = 1$ (Master/Slave)
		$I2C_STS1.ADD10F = 1$ (Master)
		$I2C_STS1.STOPF = 1$ (Slave)
		I2C_STS1.BSF = 1 with no I2C_STS1.TXDATE or I2C_STS1.RXDATNE event
		I2C_STS1.TXDATE = 1 when I2C_CTRL2.BUFINTEN = 1
		I2C_STS1.RXDATNE = 1 when I2C_CTRL2.BUFINTEN = 1
8	ERRINTEN	Error interrupt enable
		0: Disable error interrupt;
		1: Enable error interrupt.
		This interrupt is generated when:
		$I2C_STS1.BUSERR = 1;$
		I2C_STS1.ARLOST = 1;
		I2C_STS1.ACKFAIL = 1;
		I2C_STS1.OVERRUN = 1;
		$I2C_STS1.PECERR = 1;$

Bit field	Name	Description
7:6	Reserved	Reserved, the reset value must be maintained.
5:0	CLKFREQ[5:0]	I2C Peripheral clock frequency
		CLKFREQ[5:0] should be the APB clock frequency to generate the correct timming.
		000000: Disable
		000001: Disable
		000010: 2MHz
		000011: 3MHz
		110000: 48MHz
		110001~111111: Disable.

14.5.4 I2C Own address register 1 (I2C_OADDR1)

Address offset: 0x08

Bit field	Name	Description
15:13	Reserved	Reserved, the reset value must be maintained.
12	PECERR	PEC Error in reception
		Writing '0' to this bit by software can clear it, or it is cleared by hardware when
		I2C_CTRL1.EN=0.
		0: No PEC error: receiver will returns ACK (if the I2C_CTRL1.ACKEN bit is enabled)
		1: PEC error: receiver will returns NACK (It doesn't matter if I2C_CTRL1.ACKEN is enabled or
		not)
11	OVERRUN	Overrun/Underrun

Bit field	Name	Description
		Writing '0' to this bit by software can clear it, or it is cleared by hardware when
		I2C_CTRL1.EN=0.
		0: No Overrun/Underrun
		1: Overrun/Underrun
		Set by hardware in slave mode when I2C_CTRL1.NOEXTEND=1, and when receiving a new
		byte in receiving mode, if the data within DAT register has not been read yet, over-run occurs, the
		new received byte will be lost. When transmitting a new byte in transmit mode, but there is not
		new data that has not been written in DAT register, under-run occurs which leads that the same
		byte will be send twice.
10	ACKFAIL	Acknowledge failure
		Writing '0' to this bit by software can clear it, or it is cleared by hardware when
		I2C_CTRL1.EN=0.
		0: No acknowledge failed;
		1: Acknowledge failed.
9	ARLOST	Arbitration lost (master mode)
		Writing '0' to this bit by software can clear it, or it is cleared by hardware when
		I2C_CTRL1.EN=0.
		0: No arbitration lost;
		1: Arbitration lost.
		When the interface loses control of the bus, the hardware will set this bit to '1', and the I2C
		interface will automatically switch back to slave mode (I2C_STS2.MSMODE=0).
8	BUSERR	Bus error
		Writing '0' to this bit by software can clear it, or it is cleared by hardware when
		I2C_CTRL1.EN=0.
		0: No start or stop condition error
		1: Start or stop condition error
7	TXDATE	Data register empty (transmitters)
		Writing data to DAT register by software can clear this bit; Or after a start or stop condition
		occurs, or automatically cleared by hardware when I2C_CTRL1.EN=0.
		0: Data register is not empty;
		1: Data register is empty.
		When sending data, this bit is set to' 1' when the data register is empty, and it is not set at the
		address sending stage.
		If a NACK is received, or the next byte to be sent is PEC(I2C_CTRL1.PEC=1), this bit will not
		be set.
		Note: After the first data to be sent is written, or data is written when BSF is set, the TXDATE bit
		cannot be cleared, because the data register is still empty.
6	RXDATNE	Data register not empty(receivers)
-		This bit is cleared by software reading and writing to the data register, or cleared by hardware
		when I2C_CTRL1.EN=0.
		0: Data register is empty;
		1: Data register is on empty.

Bit field	Name	Description
		During receiving data, this bit is set to' 1' when the data register is not empty, and it is not set at
		the address receiving stage.
		RXDATNE is not set when the ARLOST event occurs.
		Note: When BSF is set, the RXDATNE bit cannot be cleared when reading data, because the data
		register is still full.
5	Reserved	Reserved, the reset value must be maintained.
4	STOPF	Stop detection (slave mode)
		After the software reads the STS1 register, the operation of writing to the CTRL1 register will
		clear this bit, or when I2C_CTRL1.EN=0, the hardware will clear this bit.
		0: No stop condition is detected;
		1: Stop condition is detected.
		After a ACK, the hardware sets this bit to' 1' when the slave device detects a stop condition on
		the bus.
		Note: I2C_STS1.STOPF bit is not set after receiving NACK.
3	ADDR10F	10-bit header sent (Master mode)
		After the software reads the STS1 register, the operation of writing to the CTRL1 register will
		clear this bit, or when I2C_CTRL1.EN=0, the hardware will clear this bit.
		0: No ADD10F event;
		1: Master has sent the first address byte.
		In 10-bit address mode, when the master device has sent the first byte, the hardware sets this bit
		to' 1'.
		Note: After receiving a NACK, the I2C_STS1.ADDR10F bit is not set.
2	BSF	Byte transfer finished
		After the software reads the STS1 register, reading or writing the data register will clear this bit;
		Or after sending a start or stop condition in transfer, or when I2C_CTRL1.EN=0, this bit is
		cleared by hardware.
		0: Byte transfer does not finish.
		1: Byte transfer finished.
		When I2C_CTRL1.NOEXTEND =0, the hardware sets this bit to' 1' in the following cases:
		In receiving mode, when a new byte (including ACK pulse) is received and the data register has
		not been read (I2C_STS1.RXDATNE=1).
		In sending mode, when a new data is to be transmitted and the data register has not been written
		the new data (I2C_STS1.TXDATE=1).
		Note: After receiving a NACK, the BSF bit will not be set.
		If the next byte to be transferred is PEC (I2C _STS2.TRF is' 1' and I2C_CTRL1.PEC is' 1'), the
		BSF bit will not be set.
1	ADDRF	Address sent (master mode) / matched (slave mode)
		After the STS1 register is read by software, reading the STS2 register will clear this bit, or when
		I2C_CTRL1.EN=0, it will be cleared by hardware.
		0: Address mismatch or no address received(slave mode) or Address sending did not end(master
		mode);
		1: Received addresses matched(slave mode) or Address sending ends(master mode)

Bit field	Name	Description
		In master mode:
		In 7-bit address mode, this bit is set to' 1' after receiving the ACK of the address. In 10-bit address
		mode, this bit is set to' 1' after receiving the ACK of the second byte of the address.
		In slave mode:
		Hardware sets this bit to' 1' (when the corresponding setting is enabled) when the received slave
		address matches the content in the OADDR register, or a general call is recognized.
		Note: After receiving NACK, the I2C_STS1.ADDRF bit will not be set.
0	STARTBF	Start bit (Master mode)
		After the STS1 register is read by software, writing to the data register will clear this bit, or when
		I2C_CTRL1.EN=0, the hardware will clear this bit.
		0: Start condition was not sent;
		1: Start condition has been sent.
		This bit is set to' 1' when the start condition is sent.

14.5.8 I2C Status register 2 (I2C_STS2)

Address offset: 0x18

15						8	7	6	5	4	3	2	1	0
	1	PECV	L[7:0]	1	1	1	DUAL FLAG	Rese	erved	GCALL ADDR	Reserved	TRF	BUSY	MS MODE
		:	r				r			r		r	r	r

Bit field	Name	Description
15:8	PECVAL[7:0]	Packet error checking register
		Stores the internal PEC value When I2C_CTRL1.PECEN =1.
7	DUALFLAG	Dual flag(Slave mode)
		Hardware clears this bit when a stop condition or a repeated start condition is generated, or
		when I2C_CTRL1.EN=0.
		0: Received address matches the content in OADDR1;
		1: Received address matches the content in OADDR2.
6:5	Reserved	Reserved, the reset value must be maintained.
4	GCALLADDR	General call address(Slave mode)
		Hardware clears this bit when a stop condition or a repeated start condition is generated, or
		when I2C_CTRL1.EN=0.
		0: No general call address was received;
		1: when I2C_CTRL1.GCEN=1, general call address was received.
3	Reserved	Reserved, the reset value must be maintained.
2	TRF	Transmitter/receiver
		After detecting the stop condition (I2C_STS1.STOPF=1), repeated start condition or bus
		arbitration loss (I2C_STS1.ARLOST=1), or when I2C_CTRL1.EN=0, the hardware clears it.
		0: Data receiving mode
		1: Data transmission mode;

Bit field	Name	Description
		At the end of the whole address transmission stage, this bit is set according to the R/W bit of
		the address byte.
1	BUSY	Bus busy
		Hardware clears this bit when a stop condition is detected.
		0: No data communication on the bus;
		1: Data communication on the bus.
		When detecting that SDA or SCL is low level, the hardware sets this bit to' 1';
		Note: This bit indicates the bus communication currently in progress, and this information is
		still updated when the interface is disabled (I2C_CTRL1.EN=0).
0	MSMODE	Master/slave mode
		Hardware clears this bit when a stop condition is detected on the bus, arbitration is lost
		(I2C_STS1.ARLOST=1), or when I2C_CTRL1.EN=0.
		0: In slave mode;
		1: In master mode.
		When the interface is in the master mode (I2C_STS1.STARTBF=1), the hardware sets this bit;

14.5.9 I2C Clock control register (I2C_CLKCTRL)

Address offset: 0x1c

Reset value: 0x0000

Note: The CLKCTRL register can only be set when I^2C *is turned off* ($I2C_CTRL1.EN=0$)

15	14	13	12	11											0
FSMODE	DUTY	Reserved			CLKCTRL[11:0]								1		
			I		I				L		1		1		
rw	rw								17	w					

Bit field	Name	Description						
15	FSMODE	I2C mode selection						
		0: I2C in standard mode (duty cycle default 1/1);						
		1: I2C in fast mode (duty cycle configurable).						
14	DUTY	Duty cycle in fast mode						
		0: Tlow/Thigh = 2;						
		1: Tlow/Thigh = 16/9						
13:12	Reserved	Reserved, the reset value must be maintained.						
11:0	CLKCTRL[11:0]	Clock control register in Fast/Standard mode (Master mode)						
		This division factor is used to set the SCL clock in the master mode.						
		If duty cycle = $Tlow/Thigh = 1/1$:						
		$CLKCTRL = f_{PCLK}(Hz)/100000/2$						
		Thow = CLKCTRL \times TPCLK						
		Thigh = CLKCTRL \times T _{PCLK}						
		If duty cycle = $Tlow/Thigh = 2/1$:						
		$CLKCTRL = f_{PCLK}(Hz)/100000/3$						
		The equation $T_{\text{PCLK}} = 2 \times CLKCTRL \times T_{\text{PCLK}}$						

Bit field	Name	Description
		Thigh = CLKCTRL×T _{PCLK}
		If duty cycle = $Tlow/Thigh = 16/9$:
		$CLKCTRL = f_{PCLK}(Hz)/100000/25$
		The set of
		Thigh = 9 ×CLKCTRL ×T _{PCLK}
		For example, if $f_{PCLK}(Hz) = 8MHz$, duty cycle = 1/1, CLKCTRL = $8000000/100000/2 = 0x28$.
		Note: 1. The minimum setting value is 0x04 in standard mode and 0x01 in fast mode;
		2. $T_{high} = T_{r(SCL)} + T_{w(SCLH)}$. See the definitions of these parameters in the data sheet for details.
		3. $T_{low} = T_{f(SCL)} + T_{w(SCLL)}$, see the definitions of these parameters in the data sheet for details;

14.5.10 I2C Rise time register (I2C_TMRISE)

Address offset: 0x20

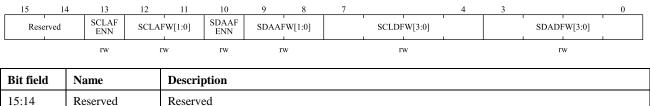

Reset value: 0x0002

15								6	5					0	
	1					1				1					
	Reserved										TMRISE[5:0]				
		1 1				1		1				1	1 1		
											r	W			

Bit field	Name	Description
15:6	Reserved	Reserved, the reset value must be maintained.
5:0	TMRISE[5:0]	Maximum rise time in fast/standard mode (master mode).
		These bits must be set to the maximum SCL rising time given in the I2C bus specification, and
		incremented step is 1.
		For example, the maximum allowable SCL rise time in standard mode is 1000ns. if the value in
		I2C_CTRL2.CLKFREQ [5:0] is equal to 0x08(8MHz) and TPCLK=125ns ,09h(1000ns/125 ns + 1)
		must be written in TMRISE[5:0].
		If the result is not an integer, write the integer part to TMRISE[5:0] to ensure the t _{HIGH} parameter.
		Note: TMRISE[5:0] can only be set when I2C is disabled (I2C_CTRL1.EN=0).

14.5.11 I2C Filter control register (I2C_GFLTRCTRL)

Address offset: 0x24

15:14	Reserved	Reserved					
13	SCLAFENN	SCL analog filter enable.					
		0: Enable					
		1: Disable					

Bit field	Name	Description
12:11	SCLAFW[1:0]	SCL analog filter width selection
		00: 5ns
		01: 15ns
		10: 25ns
		11: 35ns
10	SDAAFENN	SDA analog filter enable
		0: Enable
		1: Disable
9:8	SDAAFW[1:0]	SDA analog filter width selection
		00: 5ns
		01: 15ns
		10: 25ns
		11: 35ns
7:4	SCLDFW[3:0]	SCL digital filter width selection
	SCLDI W[5.0]	0000: Disable SCL digital filter
		Others: Filter width is SCLDFW * TPCLK
3:0	SDADFW[3:0]	SDA digital filter width selection
		0000: Disable SDA digital filter
		Others: Filter width is SDADFW * T _{PCLK}

14.5.12 **I2C master receive byte register (I2C_BYTENUM)**

Address offset: 0x28

	15	14	13									 	 	0
	BYTE NUMEN	RXFSEL		BYTENUM[13:0]										
,	rw	rw							r	N				

Bit field	Name	Description
15	BYTENUMEN	Master receive byte control enable
		0: Disable
		1: Enable
14	RXFSEL	Receive end send condition selection
		0: master sends a STOP condition after receiving all bytes
		1: master sends a START condition after receiving all bytes
13:0	BYTENUM	Master receives bytes configuration
		Note: If you need to reconfigure BYTENUM after receiving all bytes, you need to wait for
		I2C_STS2.BUSY is 0 and re-enabled I2C_CTRL1.ACKEN

15 Universal asynchronous receiver transmitter (UART)

15.1 Introduction

UART is a full-duplex universal asynchronous serial transceiver module. This interface is a highly flexible serial communication device that can perform full-duplex data exchange with external devices.

The UART has programmable transmit and receive baud rates. It also supports single-wire half-duplex communication and Multipprocessor communication.

15.2 Main features

- Full-duplex asynchronous communication
- Supports NRZ standard format
- Supports single-wire half-duplex communication
- Configurable baud rate
- Support serial data frame structure with 8 or 9 data bits, 1 or 2 stop bits
- Generation and checking of supported parity bits
- Support multi-processor communication mode, can enter mute mode, wake up by idle detection or address mark detection
- Support data overflow error detection, frame error detection, noise error detection, parity error detection
- 8 interrupt requests:
 - ♦ Transmit data register empty
 - ♦ Transmit complete
 - ♦ Receive data register full
 - ♦ Idle line detected
 - ♦ Data overflow detected
 - ♦ Frame error
 - \diamond Noise error
 - ♦ Parity error

15.3 Functional block diagram

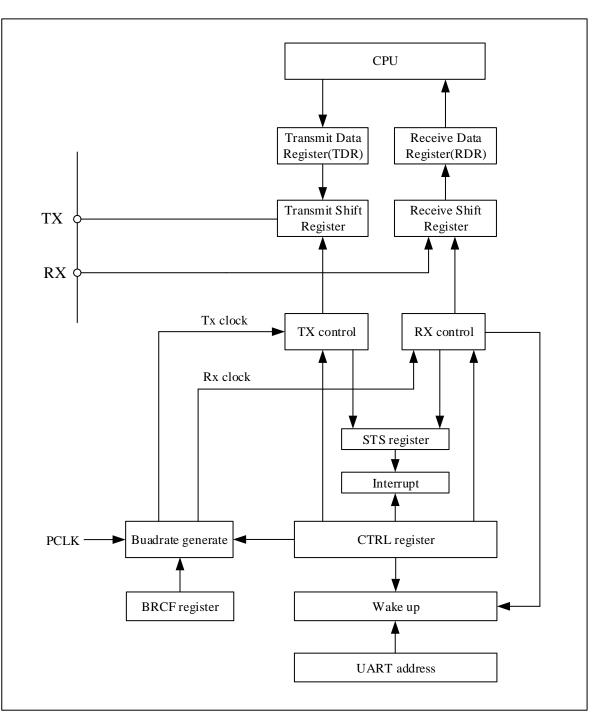

Figure 15-1 UART block diagram

15.4 Function description

As shown in the Figure 15-1, the bidirectional communication of any UART needs to use the RX and TX pins to connect to external devices. Among them, TX is the output pin for serial data transmission. When the transmitter is active and not sending data, the TX pin is pulled high. When the transmitter is inactive, the TX pin reverts to the I/O

port configuration. RX is an input pin for serial data reception, data is recovered by oversampling technique.

The data packets of serial communication are transmitted from the sending device to the RX interface of the receiving device through its own TX interface, and the bus is in an idle state before sending or receiving. Frame format is: 1 start bit + 8 or 9 data bits (least significant bit first) + 1 parity bit (optional) + 1 or 2 stop bit.

Use the fractional baud rate generator to configure transmit and receive baud rates.

15.4.1 UART frame format

The start bit of the data frame is low.

The word length can be selected as 8 or 9 bits by programming the UART_CTRL1.WL bit, least significant bit first.

The stop bit of the data frame is high.

An idle frame is a complete data frame consisting of '1's, including the start bit.

A break frame is a complete data frame consisting of '0's, including the stop bit. At the end of the break frame, the transmitter inserts 1 or 2 stop bits ('1') to acknowledge the start bit.

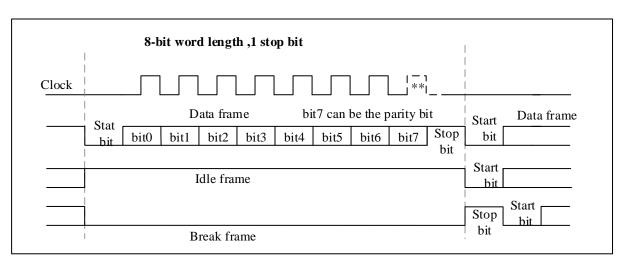

Figure 15-2 Word length = 8 setting

Figure 15-3 Word length = 9 setting

		9-b	oit word	d lengt	h , 1 st	op bit						I	
Clock	 									**

	Idle frame											Start bit	
												Stop	Start
	I		E	Break f	rame							bit	

15.4.2 Transmitter

After the transmitter is enabled, the data entered into the transmit shift register is sent out through the TX pin.

15.4.2.1 **Idle frame**

Setting UART_CTRL1.TXEN will cause the UART to transmit an idle frame before the first data frame.

15.4.2.2 Character send

Idle frames are followed by characters sent. Each character is preceded by a low start bit. The transmitter sends 8-bit or 9-bit data according to the configuration of the data bit length, with the least significant bit first. If UART_CTRL1.TXEN is reset during a data transfer, it will cause the baud rate counter to stop counting and the data being transferred will be corrupted.

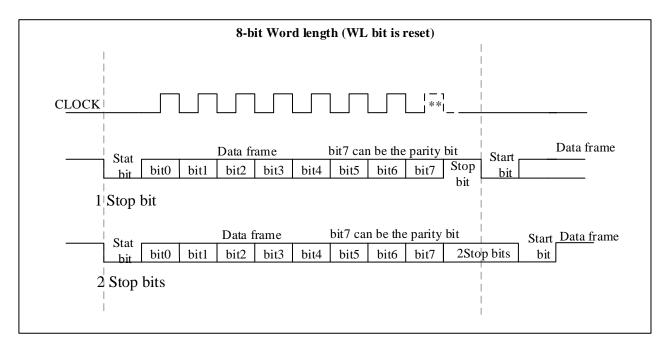

15.4.2.3 **Stop bit**

The characters are followed by stop bits, the number of which can be configured by setting UART_CTRL2. STPB[1:0] bits.

UART_CTRL2.STPB[1:0]	Stop bit length (bits)	functional description						
00	1	default						
10	2	General UART mode, single-wire mode and modem mode.						

Table 15-1 Stop bit configuration

Figure 15-4 Stop bit configuration

15.4.2.4 Break frame

Use UART_CTRL1.SDBRK to send the break frame. When there is 8-bit data, the break frame consists of 10 bits of low level, followed by a stop bit; when there is 9-bit data, the break frame consists of 11 bits of low level, followed by a stop bit.

After the break frame is sent, UART_CTRL1.SDBRK is cleared by hardware, and the stop bit of the break frame is being sent. Therefore, to send a second break frame, UART_CTRL1.SDBRK should be set after the stop bit of the previous break frame has been sent.

If software resets the UART_CTRL1.SDBRK bit before starting to send the break frame, the break frame will not be sent.

15.4.2.5 **Transmitter process**

- 1. Enable UART_CTRL1.UEN to activate UART;
- 2. Configure the transmitter's baud rate, data bit length, parity bit (optional), the number of stop bits;
- 3. Activate the transmitter (UART_CTRL1.TXEN);
- 4. Write each data to be sent to the UART_DAT register through the CPU, and the write operation to the UART_DAT register will clear UART_STS.TXDE;
- 5. After writing the last data word to the UART_DAT register, wait for UART_STS.TXC =1, which indicates the end of the transmission of the last data frame.

15.4.2.6 Single byte communication

Writing to the UART_DAT register clears the UART_STS.TXDE bit.

The UART_STS.TXDE bit is set by hardware when the data in the TDR register is transferred to the transmit shift register (indicating that data is being transmitted). An interrupt will be generated if UART_CTRL1.TXDEIEN is set. At this point, the next data can be write to the UART_DAT register because the TDR register has been cleared and will not overwrite the previous data.

Write operation to UART_DAT register:

- When the transmit shift register is not sending data and is in an idle state, the data is directly put into the shift register for transmission, and the UART_STS.TXDE bit is set by hardware;
- When the transmit shift register is sending data, the data is stored in the TDR register, and after the current transmission is completed, the data is put into the shift register.

When a frame containing data is sent and UART_STS.TXDE=1, the UART_STS.TXC bit is set to '1' by hardware. An interrupt is generated if UART_CTRL1.TXCIEN is '1'.UART_STS.TXC bit is cleared by a software sequence (read UART_STS register first, then write UART_DAT register).

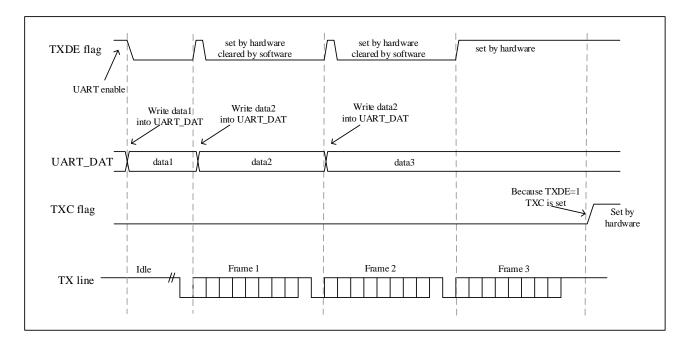

Figure 15-5 TXC/TXDE changes during transmission

15.4.3 Receiver

15.4.3.1 Start bit detection

When the received sampling sequence is: 1 1 1 0 X 0 X 0 X 0 0 0 0, it is considered that a start bit is detected.

The samples at the 3rd, 5th, and 7th bits, and the samples at the 8th, 9th, and 10th bits are all '0' (that is, 6 '0'), then confirm the receipt of the start bit, the UART_STS.RXDNE flag bit is set, and if UART_CTRL1.RXDNEIEN=1, an interruption occurs, but it will not set the NEF noise flag.

The samples of the 3rd, 5th, and 7th bits have two '0' points, and at the same time, the samples of the 8th, 9th, and 10th bits have two '0' points, then it is confirmed that the start bit is received, but it will be set bit NEF noise flag.

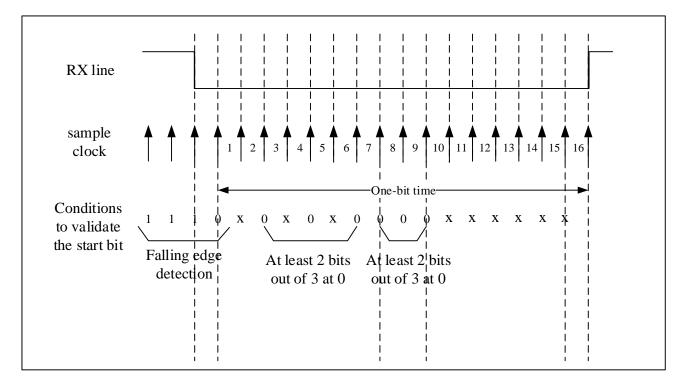

The samples of the 3rd, 5th, and 7th bits have two '0' points, and at the same time, the samples of the 8th, 9th, and 10th bits have three '0' points, then the start bit is confirmed, but it will be set NEF noise flag.

The samples of the 3rd, 5th, and 7th bits have three '0' points, and at the same time, the samples of the 8th, 9th, and 10th bits have two '0' points, then the start bit is confirmed, but it will be set NEF noise flag.

If the sampling values in the 3rd, 5th, 7th, 8th, 9th and 10th bits cannot meet the above four requirements, the UART receiver thinks that it has not received the correct start bit, and will exit the start bit detection and return to idle state and wait for falling edge.

Figure 15-6 Start bit detection

15.4.3.2 **Stop bit description**

During data reception, the number of data stop bits can be configured by the UART_CTRL2.STPB[1:0] bits. In normal mode, 1 or 2 stop bits can be selected.

- 1. **1 stop bit:** the sampling of 1 stop bit is carried out through three points, and the 8th, 9th and 10th sampling bits are selected.
- 2. **2 stop bits:** the sampling of 2 stop bits is completed at the 8th, 9th and 10th sampling points of the first stop position. If a frame error is detected during the first stop bit, the frame error flag is set. The second stop bit does not detect frame error. The UART_STS.RXNE flag will be set at the end of the first stop bit.

15.4.3.3 **Receiver process**

- 1. Enable UART_CTRL1.UEN to activate UART;
- 2. Configure the receiver's baud rate, data bit length, parity bit (optional), stop bit number;
- 3. Activate the receiver (UART_CTRL1.RXEN) and start looking for the start bit;
- 4. The receiver receives 8-bit or 9-bit data according to the configuration of the data bit length, and the least significant bit of the data is first shifted from the RX pin into the receive shift register;
- 5. When the data of the received shift register is moved to the RDR register, UART_STS.RXDNE is set, and the data can be read out. If UART_CTRL1.RXDNEIEN is 1, an interrupt will be generated;
- 6. When an overflow error, noise error, or frame error is detected in the received frame, the corresponding error flag status bit will be set. If UART_CTRL1.RXEN is reset during data transmission, the data being received will be lost;

7. UART_STS.RXDNE is set after receiving data, and a read operation to UART_DAT can clear this bit:

During single-buffer communication, it is cleared by software reading the UART_DAT register.

15.4.3.4 Idle frame detection

When an idle frame is detected, UART_STS.IDLEF sets to 1. An interrupt is generated if UART_CTRL1.IDLEIEN is '1'. UART_STS.IDLEF bit is cleared by a software sequence (read UART_STS register first, then read UART_DAT register).

15.4.3.5 Break frame detection

The frame error flag(UART_STS.FEF) is set by hardware when the receiver detects a break frame. It can be cleared by a software sequence (read UART_STS register first, then read UART_DAT register).

15.4.3.6 Framing error

A framing error occurs when a stop bit is not received and recognized at the expected time. At this time, the frame error flag UART_STS.FEF will be set by hardware, and the invalid data will be transferred from the shift register to the UART_DAT register. During single-byte communication, no framing error interrupt will be generated because it occurs with UART_STS.RXDNE and the hardware will generate an interrupt when the UART_STS.RXDNE flag is set.

15.4.3.7 **Overrun error**

When UART_STS.RXDNE is still '1', when the data currently received in the shift register needs to be transferred to the RDR register, an overflow error will be detected, and the hardware will set UART_STS.OREF. When this bit is set, the value in the RDR register is not lost, but the data in the shift register is overwritten. It is cleared by a software sequence (read UART_STS register first, then write UART_DAT register).

When an overflow error occurs, UART_STS.RXDNE is '1', and an interrupt is generated.

15.4.3.8 Noise error

UART_STS.NEF is set by hardware when noise is detected on a received frame. It is cleared by software sequence (read UART_STS register first, then write UART_DAT register). During single-byte communication, no noise interrupt generated because it occurs with UART_STS.RXDNE and the hardware will generate an interrupt when the UART_STS.RXDNE flag is set.

Sample value	NE status	Received bits	Data validity
000	0	0	Effective
001	1	0	be invalid
010	1	0	be invalid
011	1	1	be invalid
100	1	0	be invalid
101	1	1	be invalid
110	1	1	be invalid
111	0	1	Effective

Table 15-2 Data sampling for noise detection

15.4.4 Generation of fractional baud rate

The baud rate of the UART can be configured in the UART_BRCF register. This register defines the integer and fractional parts of the baud rate divider. The baud rate of the transmitter and receiver should be configured to the same value. Be careful not to change the value of the UART_BRCF register during communication, because the baud rate counter will be replaced by the new value of the baud rate register.

TX / RX baud rate = f_{CK} /(16 *UARTDIV)

where f_{CK} is the clock provided to the peripheral: PCLK is used for UART1/2, up to 48MHz. UARTDIV is an unsigned fixed-point number.

15.4.4.1 UARTDIV and UART_BRCF register configuration

Example 1:

If UARTDIV = 27.75, then:

 $DIV_Decimal = 16*0.75 = 12 = 0x0C$

 $DIV_Integer = 27=0x1B$

So UART_BRCF = 0x1BC

Example 2:

If UARTDIV = 20.98, then:

DIV_Decimal = 16*0.98 = 15.68

Nearest integer: DIV_Decimal = 16 = 0x10, out of configurable range, so a carry to integer is required

So DIV_Integer = 20 + 1 = 21 = 0x15

 $DIV_Decimal = 0x0$

So UART_BRCF = 0x150

Example 3:

If UART_BRCF = 0x19B:

 $DIV_Integer = 0x19 = 25$

 $DIV_Decimal = 0x0B = 11$

So UARTDIV = 25 + 11/16 = 25.6875

Table 15-3 Error calculation when setting baud rate

Ba	ud rate	f _{ck} =48M									
serial number	Kbps	reality	Set baud rate	Error%

Notes: The lower the clock frequency of the CPU, the lower the error for a particular baud rate.

15.4.5 Receiver's tolerance clock deviation

Variations due to transmitter errors (including transmitter side oscillator variations), receiver side baud rate rounding errors, receiver side oscillator variations, variations due to transmission lines (usually due to the inconsistency between the low-to-high transition timing of the transceiver and the high-to-low transition timing of the transceiver), these factors will affect the overall clock system variation. Only when the sum of the above four changes is less than the tolerance of the UART receiver, the UART asynchronous receiver can work normally.

When receiving data normally, the tolerance of the UART receiver depends on the selection of the data bit length and whether it is generated using a fractional baud rate. The tolerance of the UART receiver is equal to the maximum tolerable variation.

Table 15-4 When DIV_Decimal = 0. Tolerance of UART receiver

WL bit	NF is an error	NF is don't care						
0	3.75%	4.375%						
1	3.41%	3.97%						

Table 15-5 When DIV_Decimal != 0. Tolerance of UART receiver

WL bit	NF is an error	NF is don't care						
0	3.33%	3.88%						
1	3.03%	3.53%						

15.4.6 Parity control

Parity can be enabled by configuring the UART_CTRL1.PCEN bit.When the parity bit is enabled for transmission, A parity bit is generated, parity check is performed on reception.

Table 15-6 Frame format

WL bit	PCEN bit	UART frame
0	0	Start bit 8-bit data Stop bit
0	1	Start bit 7 bits of data Parity bit Stop bit
1	0	Start bit 9-bit data Stop bit
1	1	start bit 8-bit data Parity bit Stop bit

Even parity

Configure UART_CTRL1.PSEL to 0, and even parity can be selected.

Make the number of '1' in the transmitted data (including parity bit) be an even number. That is: if Data=1100 0101, there are 4 '1's, then the parity bit will be '0' (4 '1' in total). After the data and check digit are sent to the receiver, the receiver calculates the number of 1s in the data again. If it is an even number, the check is passed, indicating that no errors occurred during the transmission process. If it is not even, it means that an error has occurred, the UART_STS.PEF flag is set to '1', and if UART_CTRL1.PEIEN is enabled, an interrupt is generated.

Odd parity

Configure UART_CTRL1.PSEL to 1, you can choose odd parity.

Make the number of '1' in the transmitted data (including parity bit) be an odd number. That is: if Data=11000101, there are 4 '1's, then the parity bit will be '1' (5 '1' in total). After the data and check digit are sent to the receiver, the receiver calculates the number of 1s in the data again. If it is an odd number, the check is passed, indicating that no errors occurred during the transmission process. If it is not an odd number, it means that an error has occurred, the UART_STS.PEF flag is set to '1', and if UART_CTRL1.PEIEN is enabled, an interrupt is generated.

15.4.7 Multiprocessor communication

UART allows multiprocessor communication. The principle is: multiple processors communicate through UART, and it is necessary to determine who is the master device, and the remaining processors are all slave devices. The TX output of the master device is directly connected to the RX port of all slave device. The TX outputs of the slaves are logically AND together and connected to the RX inputs of the master.

When multi-processor communication is performed, the slave devices are all in mute mode, and the host uses a specific method to wake up a slave device to be communicated when needed, so that the slave device is in an active state and transmits data with the master device.

The UART can wake up from mute mode by idle line detection or address mark detection.

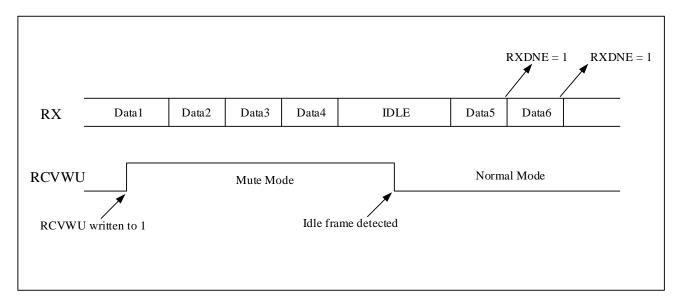

15.4.7.1 **Idle line detection**

The idle line detection configuration process is as follows:

- 1. Configure the UART_CTRL1.WUM bit to 0, and the UART performs idle line detection;
- 2. When UART_CTRL1.RCVWU is set (which can be automatically controlled by hardware or written by software under certain conditions), UART enters mute mode. In mute mode, none of the receive status bits are set, and all receive interrupts are disabled;
- 3. As shown in the Figure 15-7 below, when an idle frame is detected, UART is woken up, and then UART_CTRL1.RCVWU is cleared by hardware. At this time, UART_STS.IDLEF is not set.

Figure 15-7 Mute mode using idle line detection

15.4.7.2 Address mark detection

By configuring the UART_CTRL1.WUM bit to 1, the UART performs address mark detection. The address of the receiver is programmable through the UART_CTRL2.ADDR[3:0] bits. If the MSB is 1, the byte is considered an address, otherwise it is considered data.

In this mode, the UART can enter mute mode by:

When the receiver does not contain data, UART_CTRL1.RCVWU can be written to 1 by software, and UART enters mute mode;

Note: When the receive buffer contains no data ($UART_STS.RXDNE = 0$), the $UART_CTRL1.RCVWU$ bit can be written to 0 or 1. Otherwise, the write operation is ignored.

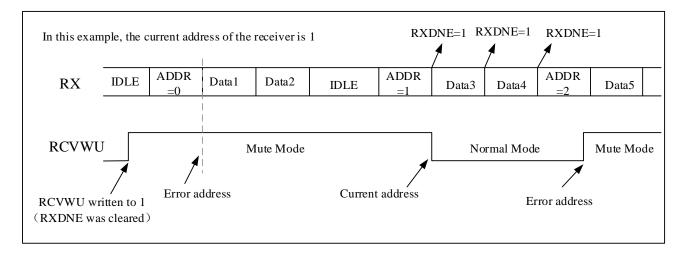

■ When the received address does not match the address of the UART_CTRL2.ADDR[3:0] bits, UART_CTRL1.RCVWU is written to 1 by hardware.

In mute mode, none of the receive status bits are set and all receive interrupts are disabled.

When the received address matches the address of the UART_CTRL2.ADDR[3:0] bits, the UART is woken up and UART_CTRL1.RCVWU is cleared. The UART_STS.RXDNE bit will be set when this matching address is received. Data can then be transmitted normally.

Figure 15-8 Mute mode detected using address mark

15.4.8 Single-line half-duplex communication

UART supports single-wire half-duplex communication, allowing data to be transmitted in both directions, but only allows data to be transmitted in one direction at the same time. Communication conflicts are managed by software. Through the UART_CTRL3.HDMEN bit, you can choose whether to enable half-duplex mode.

After the half-duplex mode is turned on, the TX pin and the RX pin are interconnected inside the chip, and the RX pin is no longer used. When there is no data to transmit, TX is always released. Therefore, when not driven by the UART, the TX pin must be configured as a floating input or an open-drain output high.

15.5 Interrupt request

The various interrupt events of UART are logical OR relations, if the corresponding enable control bit is set, these events can generate their own interrupts, but only one interrupt request can be generated at the same time.

Interrupt function	Interrupt event	Event flag	Enable bit			
	Transmission data register is empty.	TXDE	TXDEIEN			
	Transmission complete	TXC	TXCIEN			
UADT alabal interment	Receive data ready to be read	RXDNE	RXDNEIEN			
UART global interrupt	Data overrun error detected.	OREF	KADINEIEN			
	Idle line detected	IDLEF	IDLEIEN			
	Parity error	PEF	PEIEN

		Reserved					TXDE	TXC	RXDNE	IDLEF	OREF	NEF	FEF	PEF	
								r	rc_w0	rc_w0	r	r	r	r	r

Bit field	Name	Describe
31:8	Reserved	Reserved, the reset value must be maintained
7	TXDE	The Transmit data register empty.
		Set to 1 after power-on reset or data to be sent has been sent to the shift register. Setting
		UART_CTRL1.TXDEIEN will generate an interrupt.
		This bit is cleared to 0 when the software writes the data to be sent into UART_DAT.
		0: Send data buffer is not empty.
		1: The transmitting data buffer is empty.
6	TXC	Transmission complete.
		This bit is set to 1 after power-on reset. If UART_STS.TXDE is set, this bit is set when the
		current data transmission is completed. Setting UART_CTRL1.TXCIEN bit will generate an
		interrupt.
		This bit is cleared by software sequence (a read from the UART_STS register followed by a
		write to the UART_DAT register) or software writes 0.
		0: Transmitting did not complete.
		1: Send completed.
5	RXDNE	The Read data register not empty.
		This bit is set when the read data buffer receives data from the shift register. When
		UART_CTRL1.RXDNEIEN bit is set, an interrupt will be generated.
		Software can clear this bit by writing 0 to it or reading the UART_DAT register.
		0: The read data buffer is empty.
		1: The read data buffer is not empty.
4	IDLEF	IDLE line detected flag.
		Within one frame time, the idle state is detected at the RX pin, and this bit is set to 1. When
		UART_CTRL1.IDLEIEN bit is set, an interrupt will be generated.
		The software can clear this bit by reading UART_STS first and then reading UART_DAT.
		0: No idle frame detected.
		1: idle frame detected.
		Note: UART_STS.IDLEF bit will not be set high again until UART_STS.RXDNE bit is set
		(that is, an idle line is detected again)
3	OREF	Overrun error
		With UART_STS.RXDNE set, this bit is set if the UART_DAT register receives data from
		the shift register. When UART_CTRL1.RXDNEIEN bit is set, an interrupt will be
		generated.
		The software can clear this bit by reading UART_STS first and then reading UART_DAT.
		0: No overrun error was detected.
		1: Overflow error detected.

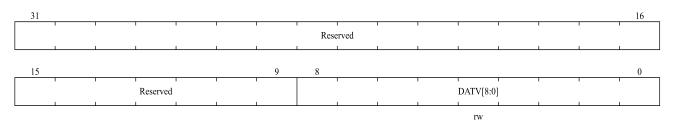

Bit field	Name	Describe
		Note: When this bit is set, the RDR register content will not be lost but the shift register will
		be overwritten.
2	NEF	Noise error flag.
		When noise is detected in the received frame, this bit is set by hardware. It is cleared by the
		software sequence (read first UART_STS, read UART_DAT again).
		0: No noise error detected.
		1: Noise error detected.
		Note: this bit will not generate an interrupt because it appears with UART_STS.RXDNE,
		and the hardware will generate an interrupt when setting the UART_STS.RXDNE flag.
1	FEF	Framing error.
		This bit is set by hardware when synchronization dislocation, excessive noise or break
		character is detected. It is cleared by the software sequence (read first UART_STS, read
		UART_DAT again).
		0: No framing errors were detected.
		1: A framing error or a Break Character is detected.
		Note: this bit will not generate an interrupt because it appears with UART_STS.RXDNE,
		and the hardware will generate an interrupt when setting the UART_STS.RXDNE flag. If the
		currently transmitted data has both framing errors and overload errors, the hardware will
		continue to transmit the data and only set the UART_STS.OREF flag bit.
0	PEF	Parity error.
		This bit is set when the parity bit of the received data frame is different from the expected
		check value. If UART_CTRL1.PEIEN=1, it will be generate an interrupt.
		The software can clear this bit by reading UART_STS first and then reading UART_DAT.
		Before clear UART_STS.PEF bit, software must wait for UART_STS.RXDNE =1.
		0: No parity error was detected.
		1: Parity error detected.

15.7.3 UART data register (UART_DAT)

Address offset: 0x04

Reset value: undefined (uncertain value)

 Bit field
 Name
 Description

 31:9
 Reserved
 Reserved, the reset value must be maintained

 8:0
 DATV[8:0]
 Data value

 Contains the data sent or received; Software can change the transmitted data by writing

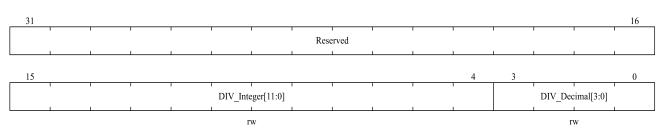

Bit field	Name	Description
		these bits, or read the values of these bits to obtain the received data.
		If parity is enabled, when the transmitted data is written into the register, the highest bit of
		the data (the 7th or 8th bit depends on UART_CTRL1.WL bit) will be replaced by the parity
		bit.

15.7.4 UART baud rate configuration register (UART_BRCF)

Address offset: 0x08

Reset value: 0x0000 0000

Note: The baud counter stops counting if UART_CTRL1.TXEN or UART_CTRL1.RXEN are disabled respectively.

13	UEN	UART enable
		When this bit is cleared, the divider and output of UART stop working after the current
		byte transmission is completed to reduce power consumption. Software can set or clear
		this bit.
		0:UART is disabled.
		1:UART is enabled.
12	WL	Word length.

Bit field	Name	Describe
		0: 8 data bits.
		1: 9 data bits.
		Note: If data is in transit, this bit cannot be configured.
11	WUM	Wake up mode from mute mode.
		0: Idle frame wake-up.
		1: Address identifier wake-up.
10	PCEN	Parity control enable
		0: Parity control is disabled.
		1: Parity control is enabled.
9	PSEL	Parity selection.
		0: Even parity.
		1: Odd parity.
8	PEIEN	PE interrupt enable
		If this bit is set to 1, an interrupt is generated when UART_STS.PEF bit is set.
		0: Parity error interrupt is disabled.
		1: Parity error interrupt is enabled.
7	TXDEIEN	TXDE interrupt enable
		If this bit is set to 1, an interrupt is generated when UART_STS.TXDE bit is set.
		0: Send buffer empty interrupt is disabled.
		1: Send buffer empty interrupt is enabled.
6	TXCIEN	Transmit complete interrupt enable.
		If this bit is set to 1, an interrupt is generated when UART_STS.TXC is set.
		0: Transmission completion interrupt is disabled.
		1: Transmission completion interrupt is enabled.
5	RXDNEIEN	RXDNE interrupt enable
		If this bit is set to 1, an interrupt is generated when UART_STS.RXDNE or
		UART_STS.OREF is set.
		0: Data buffer non-empty interrupt and overrun error interrupt are disabled.
		1: Data buffer non-empty interrupt and overrun error interrupt are enabled.
4	IDLEIEN	IDLE interrupt enable.
		If this bit is set to 1, an interrupt is generated when UART_STS.IDLEF is set.
		0: IDLE line detection interrupt is disabled.
		1: IDLE line detection interrupt is enabled.
3	TXEN	Transmitter enable.
		0: The transmitter is disabled.
		1:The transmitter is enabled.
2	RXEN	Receiver enable
		0: The receiver is disabled.
		1: The receiver is enabled.
1	RCVWU	The receiver wakes up
		Software can set this bit to 1 to make UART enter mute mode, and clear this bit to 0
		to wake up UART.
	4	-

Bit field	Name	Describe
		In idle frame wake-up mode (UART_CTRL1.WUM=0), this bit is cleared by hardware
		when an idle frame is detected.
		In address wake-up mode (UART_CTRL1.WUM=1), when an address matching frame is
		received, this bit is cleared by hardware. Or when an address mismatch frame is received, it
		is set to 1 by hardware.
		0: The receiver is in normal operation mode.
		1: The receiver is in mute mode.
0	SDBRK	Send Break Character.
		The software transmits a break character by setting this bit to 1.
		This bit is cleared by hardware during stop bit of the break frame transmission.
		0: No break character was sent.
		1: Send a break character.

2:0	Reserved	Reserved, the reset value must be maintained.

16 Serial peripheral interface (SPI)

16.1 SPI introduction

Serial peripheral interface (SPI) is able to work in master or slave mode, support full-duplex and simplex high-speed communication mode.

16.2 SPI main features

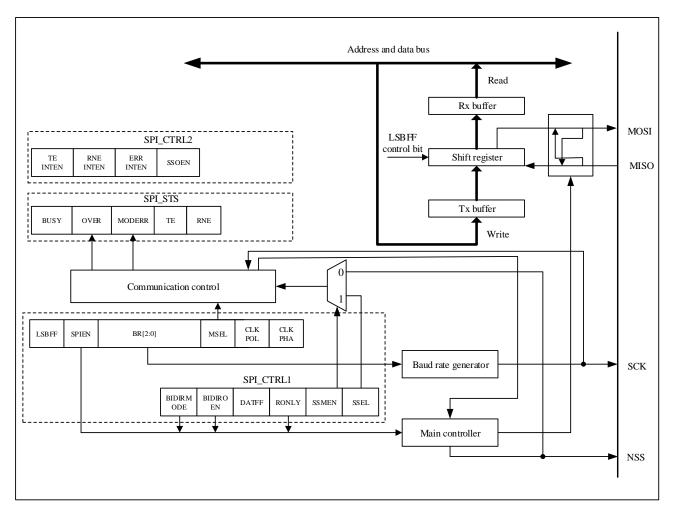

- Full duplex mode and simplex synchronous mode.
- Support master mode, slave mode and multi-master mode.
- Supports 8-bit or 16-bit data frame format.
- Data bit sequence programmable.
- NSS management by hardware or software.
- Clock polarity and phase programmable.

16.3 SPI function description

16.3.1 General description

Figure 16-1 SPI block diagram

To connected external devices, SPI has four pins, which are as follows:

- SCK: serial clock pin. Serial clock signal is output from the SCK pin of master device and input to SCK pin of slave device.
- MISO: master input/slave output pin. Data is received from the MISO pin of master device and send by the MISO pin of slave device.
- MOSI: master output/slave input pin. Data is send by the MOSI pin of master device and received from the MOSI pin of slave device.
- NSS: chip select pin. There are two types of NSS pin, internal pin and external pin. If the internal pin detects a high level, SPI works in the master mode. Conversely, SPI works in the slave mode. Users can use a standard I/O pin of the master device to control the NSS pin of the slave device.

16.3.1.1 Software NSS mode

The software slave device management is enabled when SPI_CTRL1.SSMEN=1.

The NSS pin is not used in software NSS mode. In this mode the internal NSS signal level is driven by writing the SPI_CTRL1.SSEL bit (master mode SPI_CTRL1.SSEL=1, slave mode SPI_CTRL1.SSEL=0).

16.3.1.2 Hardware NSS mode

The software slave device management is disabled when SPI_CTRL1.SSMEN=0.

Input mode: The NSS output of the master device is disabled (SPI_CTRL1.MSEL=1, SPI_CTRL2.SSOEN=0), allowing operation in multi-master mode. The master should connect NSS pin to the high level and the slave should connect NSS pin to the low level during the entire data frame transfer.

Output mode: NSS output of the master device is enable (SPI_CTRL1.MSEL=1, SPI_CTRL2.SSOEN=1). SPI as the master device must pull the NSS pin to low level, all device which connected to the master device and set to NSS hardware mode, will detect low level and enter the slave mode automatically. If the master device cannot pull the NSS pin to low level, device will enter the slave mode and generates the master mode failure error.

Note: The choice of software mode or hardware mode depends on whether NSS control is needed in the communication protocol. If not, you can choose the software mode, and release a GPIO pin for other purposes.

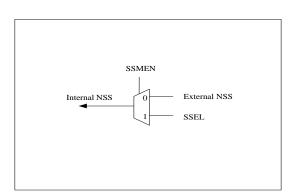

Figure 16-2 Slave selects management of hardware/software

The following figure is an example of the interconnection of single master and single slave devices

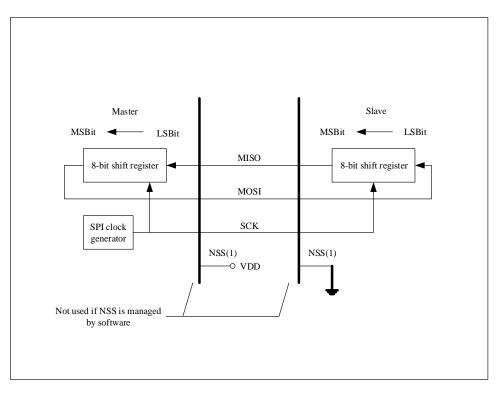

Figure 16-3 Master and slave applications

Note: NSS pin is set as input

SPI is a ring bus structure, and the master device outputs a synchronous clock signal through SCK pin, the MOSI pin of master device is connected with the MOSI pin of slave device, and the MISO pin of master device is connected with the MISO pin of slave device. Serial transfer of data between master device and slave device, through MOSI pin to send data to slave device, through MISO pin send the highest bit of the shift register of the slave device to lowest bit of the shift register of the master device, when the second bit of data is sent, the lowest bit data of the shift register will be shifted to the left by one bit and the data of the new highest bit int the shift register will be shifted to the left by one bit data of the shift register of the master device will be shifted to the left bit data of the shift register of the master device will be shifted to the left by one bit and the shift register of the master device will be shifted to the left by one bit and the shift register of the master device will be shifted to the left by one bit data of the shift register of the master device will be shifted to the left by one bit and the shift register of the master device will be shifted to the left by one bit data of the shift register of the master device will be shifted to the left by one bit and the new data that the master device has been received will be stored in the lowest bit of the shift register.

16.3.1.3 **SPI timing mode**

User can selects the clock edge of data capture by setting SPI_CTRL1.CLKPOL bit and SPI_CTRL1.CLKPHA bit.

- When CLKPOL = 0, CLKPHA = 0, the SCK pin will keep low in idle state, and the data will be sampled at the first edge, which is rising edge.
- When CLKPOL = 0, CLKPHA = 1, the SCK pin will keep low in idle state, and the data will be sampled at the second edge, which is falling edge.
- When CLKPOL = 1, CLKPHA = 0, the SCK pin will keep high in idle state, and the data will be sampled at the first edge, which is falling edge.
- When CLKPOL = 1, CLKPHA = 1, the SCK pin will keep high in idle state, and the data will be sampled at the second edge, which is rising edge.

Regardless of the timing mode used, the master and slave configuration must be the same.

Figure 16-4 is the combination timing of four CLKPHA and CLKPOL bits transmitted by SPI when the SPI_CTRL1.LSBFF=0.

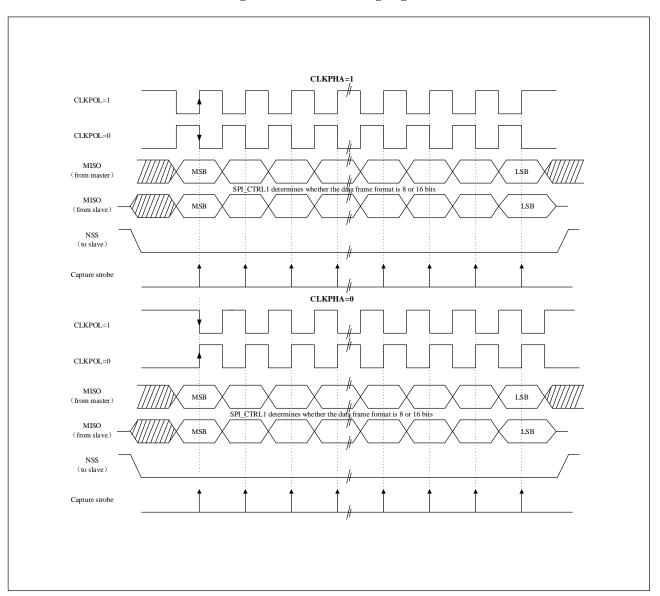

Figure 16-4 Data clock timing diagram

16.3.1.4 **Data format**

User can selects the data bit order by setting the SPI_CTRL1.LSBFF bit. When SPI_CTRL1.LSBFF = 0, SPI will send the high-order data (MSB) first; When SPI_CTRL1.LSBFF = 1, SPI will send low-order data (LSB) first.

User can selects the data frame format by setting the SPI_CTRL1.DATFF bit. When SPI_CTRL1.DATFF = 0, SPI data frame length is 8-bit; When SPI_CTRL1.DATFF = 1, SPI data frame length is 16-bit

16.3.2 SPI work mode

16.3.2.1 Master full duplex mode

Master full duplex mode (SPI_CTRL1.MSEL=1 (master), SPI_CTRL1.BIDIRMODE=0 (two-wire one-way),

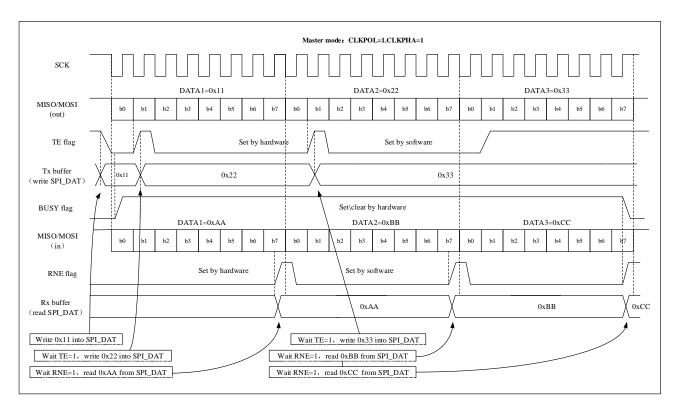

SPI_CTRL1.RONLY=0 (sending mode and receiving mode)). After the first data is written to the SPI_DAT register, the transmission will start. When the first bit of the data is sent, the data bytes are loaded from the data register into the shift register in parallel, and then according to the configuration of the SPI_CTRL1.LSBFF bit, the data bits follow the MSB or LSB order is serially shifted to the MOSI pin. At the same time, the data received on the MISO pin is serially shifted into the shift register in the same order and then loaded into the SPI_DAT register in parallel. The software operation process is as follows:

- 1. Enable SPI module, set SPI_CTRL1.SPIEN = 1.
- 2. Write the first data to be sent into SPI_DAT register (this operation will clear SPI_STS.TE bit).
- 3. Wait for SPI_STS.TE bit to be set to '1', and write the second data to be sent into SPI_DAT. Wait for SPI_STS.RNE bit to be set to '1', read SPI_DAT to get the first received data, and the SPI_STS.RNE bit will be cleared by hardware while reading SPI_DAT. Repeat the above operation, sending subsequent data and receiving n-1 data at the same time;
- 4. Wait for SPI_STS.RNE bit to be set to '1' to receive the last data;
- 5. Wait for SPI_STS.TE to be set to '1', then wait for SPI_STS.BUSY bit to be cleared and turn off SPI module.

The process of data sending and data receiving can also be implemented in the interrupt handler generated by the rising edge of the SPI_STS.RNE or SPI_STS.TE flag.

Figure 16-5 Schematic diagram of the change of TE/RNE/BUSY when the host is continuously transmitting in full duplex mode

16.3.2.2 Master two-wire one-way send-only mode

Master two-wire one-way send-only mode (SPI_CTRL1.MSEL = 1(master), SPI_CTRL1.BIDIRMODE = 0(two-wire one-way), SPI_CTRL1.RONLY = 0(sending mode and receiving mode)). Master two-wire one-way send-only mode is similar to master full-duplex mode. The difference is that this mode will not read the received data, so the

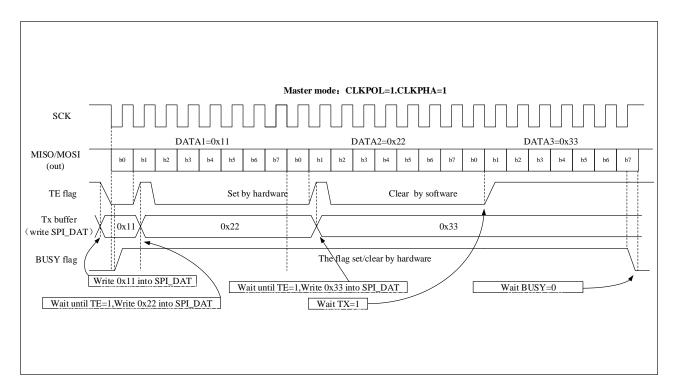

SPI_STS.OVER bit will be set to '1', and the software will ignore it. The software operation process is as follows:

- 1. Enable SPI module, set SPI_CTRL1.SPIEN = 1.
- 2. Write the first data to be sent into SPI_DAT register (this operation will clear SPI_STS.TE bit).
- 3. Wait for SPI_STS.TE bit to be set to '1', and write the second data to be sent into SPI_DAT. Repeat this operation to send subsequent data;
- 4. After writing the last data to SPI_DAT, wait for SPI_STS.TE bit to set '1'; then wait for SPI_STS.BUSY bit to be cleared to complete the transmission of all data.

The process of data sending can also be implemented in the interrupt handler generated by the rising edge of the SPI_STS.TE flag.

Figure 16-6 Schematic diagram of TE/BUSY change when the host transmits continuously in one-way only mode

16.3.2.3 Master two-wire one-way receive-only mode

Master two-wire one-way receive-only mode (SPI_CTRL1.MSEL = 1(master), SPI_CTRL1.BIDIRMODE = 0(two-wire one-way), SPI_CTRL1.RONLY = 1(receive-only mode)). When SPI_CTRL1.SPIEN=1, the receiving process starts. The data bits from the MISO pin are sequentially shifted into the shift register and then loaded into the SPI_DAT register(receive buffer) in parallel. The software operation process is as follows:

- 1. Enable the receive-only mode (SPI_CTRL1.RONLY=1).
- 2. Enable SPI module, set SPI_CTRL1.SPIEN=1:
 - In master mode, SCK clock signal is generated immediately, and serial data is continuously received before SPI is turned off(SPI_CTRL1.SPIEN=0);
 - In slave mode, serial data is continuously received when the SPI master device pulls low the NSS signal

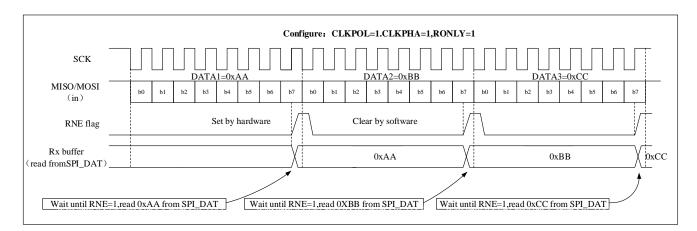

and generates SCK clock.

3. Wait for SPI_STS.RNE bit to be set to '1', read the SPI_DAT register to get the received data, and the SPI_STS.RNE bit will be cleared by hardware while reading SPI_DAT register. Repeat this operation to receive all data.

The process of data receiving can also be implemented in the interrupt handler generated by the rising edge of the SPI_STS.RNE flag.

Figure 16-7 Schematic diagram of RNE change when continuous transmission occurs in receive-only mode (BIDIRMODE=0 and RONLY=1)

16.3.2.4 Master one-wire bidirectional send mode

Master one-wire bidirectional send mode (SPI_CTRL1.MSEL = 1(master), SPI_CTRL1.BIDIRMODE = 1(one-wire bidirectional), SPI_CTRL1.BIDIROEN = 1(send-only mode), SPI_CTRL1.RONLY = 0(sending mode and receiving mode)). After the data is written to the SPI_DAT register (send buffer), the transmission process starts. This mode does not receive data. At the same time as the first data bit is send, the data to be sent is loaded into the 8-bit shift register in parallel, and then according to the configuration of the SPI_CTRL1.LSBFF bit, the SPI serially shifts the data bits to the MOSI pin in MSB or LSB order

The software operation flow of the master one-wire bidirectional send mode is the same as that of the send-only mode.

16.3.2.5 Master one-wire bidirectional receive mode

Master one-wire bidirectional receive mode (SPI_CTRL1.MSEL = 1(master), SPI_CTRL1.BIDIRMODE = 1(onewire bidirectional), SPI_CTRL1.BIDIROEN = 0(receive-only mode), SPI_CTRL1.RONLY = 0(sending mode and receiving mode)). When SPI_CTRL1.SPIEN=1, the receiving process starts. There is no data output in this mode, the received data bits are sequentially and serially shifted into the shift register, and then loaded into the SPI_DAT register (receive buffer) in parallel

The software operation flow of the master one-wire bidirectional receive mode is the same as that of the receive-only mode.

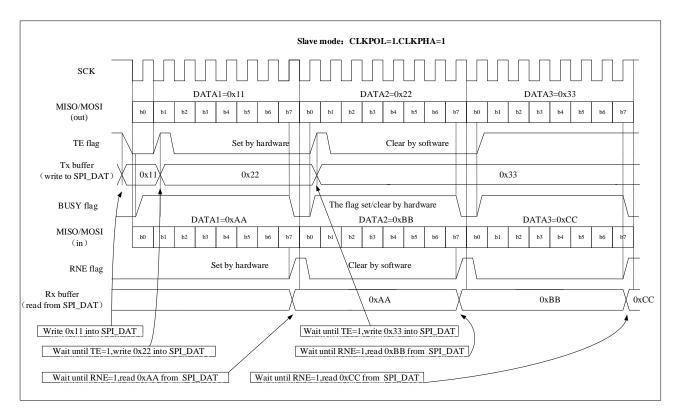

16.3.2.6 Slave full duplex mode

Slave full duplex mode (SPI_CTRL1.MSEL = 0(slave), SPI_CTRL1.BIDIRMODE = 0(two-wire one-way) and

 $SPI_CTRL1.RONLY = 0$ (sending mode and receiving mode)). The data transfer process begins when the slave device receives the first clock edge. Before the master starts data transfer, software must ensure that the data to be send is written to the SPI_DAT register.

16.3.2.7 Slave two-wire one-way send-only mode

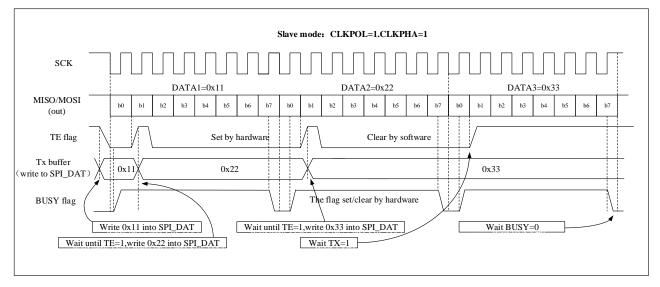

Slave two-wire one-way send-only mode (SPI_CTRL1.MSEL = 0(slave), SPI_CTRL1.BIDIRMODE = 0(two-wire one-way) and SPI_CTRL1.RONLY = 0(sending mode and receiving mode)).

Figure 16-9 Schematic diagram of TE/BUSY change during continuous transmission in slave unidirectional transmit-only

mode

16.3.2.8 Slave two-wire one-way receive-only mode

Slave two-wire one-way receive-only mode (SPI_CTRL1.MSEL = 0(slave), SPI_CTRL1.BIDIRMODE = 0(twowire one-way) and SPI_CTRL1.RONLY = 1(receive-only mode)).The data receiving process begins when the slave device receives the clock signal and the first data bit from the MOSI pin. The received data bits are sequentially and consecutively shifted serially into the shift register and then loaded into the SPI_DAT register (receive buffer) in parallel.

16.3.2.9 Slave one-wire bidirectional send mode

Slave one-wire bidirectional send mode (SPI_CTRL1.MSEL = 0(slave), SPI_CTRL1.BIDIRMODE = 1(one-wire bidirectional) and SPI_CTRL1.BIDIROEN = 1(send-only mode)).When the slave device receives the first edge of the clock signal, the sending process starts. No data is received in this mode, and the software must ensure that the data to be sent has been written in the SPI_DAT register before the SPI master device starts data transmission.

16.3.2.10 Slave one-wire bidirectional receive mode

Slave one-wire bidirectional receive mode (SPI_CTRL1.MSEL = 0(slave), SPI_CTRL1.BIDIRMODE = 1(one-wire bidirectional) and SPI_CTRL1.BIDIROEN = 0(receive-only mode)). Data receiving begins when the slave device receives the first clock edge and a data bit from the MISO pin. There is no data output in this mode, the received data bits are sequentially and consecutively shifted serially into the shift register, and then loaded into the SPI_DAT register (receive buffer) in parallel.

Note: The software operation process of the slave can refer to the master.

16.3.2.11 SPI initialization process

- 1. The baud rate of serial clock is defined by the SPI_CTRL1.BR[2:0] bits (this step is ignored if it is working in slave mode).
- 2. Select SPI_CTRL1.CLKPOL bit and SPI_CTRL1.CLKPHA bit to define the phase relationship between data transmission and serial clock.

- 3. Set SPI_CTRL1.DATFF bit to define 8-bit or 16-bit data frame format.
- 4. Configure SPI_CTRL1.LSBFF bit to define whether the sequence of sending data bits is LSB or MSB.
- 5. Configure the NSS mode.
- 6. Run mode is configured by SPI_CTRL1.MSEL bit, SPI_CTRL1.BIDIRMODE bit, SPI_CTRL1.BIDIROEN bit and SPI_CTRL1.RONLY bit.
- 7. Set the SPI_CTRL1.SPIEN=1 to enable SPI.

16.3.2.12 Basic send and receive process

When SPI sends a data frame, it first loads the data frame from the data buffer into the shift register, and then starts to send the loaded data. When the data is transferred from the send buffer to the shift register, the send buffer empty flag is set (SPI_STS.TE=1), and the next data can be loaded into the send buffer; if the SPI_CTRL2.TEINTEN bit is set, an interrupt will be generated; writing data to the SPI_DAT register will clear the SPI_STS.TE bit.

At the last edge of the sampling clock, when the data is transferred from the shift register to the receive buffer, the receive buffer non-empty flag is set (SPI_STS.RNE=1), at this time the data is ready and can be read from the SPI_DAT register; if the receive buffer non-empty interrupt is enabled (SPI_CTRL2.RNEINTEN=1), an interrupt will be generated; the SPI_STS.RNE bit can be cleared by reading the SPI_DAT register data.

In master mode, the sending process starts when data is written to the send buffer. If the next data has been written into the SPI_DAT register before the current data frame sending is completed, the continuous sending function can be achieved.

In slave mode, the NSS pin level is low, and the sending process starts when the first edge of the clock signal comes. To avoid accidental data transfers, software must write data to the send buffer before the data sending (it is recommended to enable the SPI slave before the master sends the clock).

In some configurations, when the last data is sent, the SPI_STS.BUSY flag can be used to wait for the end of the data sending.

16.3.2.13 Continuous and discontinuous transmission

When sending data in master mode, if the software is fast enough to detect each SPI_STS.TE rising edge (or TE interrupt), and the data is written to the SPI_DAT register immediately before the end of the ongoing transmission. At this time, the SPI clock remains continuous between the transmission of data items, and the SPI_STS.BUSY bit will not be cleared, continuous communication can be achieved.

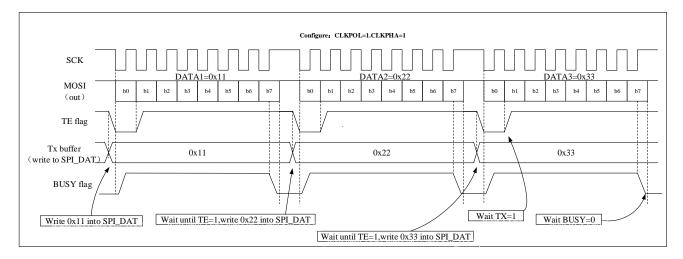

If the software is not fast enough, it will result in discontinuous communication; in this case, the SPI_STS.BUSY bit is cleared between the transmission of each data items(see Figure 16-10).

In master receive-only mode (SPI_CTRL1.RONLY=1), communication is always continuous and the SPI_STS.BUSY flag is always high.

In slave mode, the continuity of communication is determined by the SPI master device. However, even if the communication is continuous, the SPI_STS.BUSY flag will be low for at least one SPI clock cycle between each data item (see Figure 16-9).

Figure 16-10 Schematic diagram of TE/BUSY change when BIDIRMODE = 0 and RONLY = 0 are transmitted discontinuously

16.3.3 Status flag

The SPI_STS register has 3 flag bits to monitor the status of the SPI:

16.3.3.1 Send buffer empty flag bit (TE)

When the send buffer is empty, the SPI_STS.TE flag is set to 1, which means that new data can be written into the SPI_DAT register. When the send buffer is not empty, the hardware will clear this flag to 0.

16.3.3.2 **Receive buffer non-empty flag bit (RNE)**

When the receive buffer is not empty, the SPI_STS.RNE flag is set to 1, so the user knows that there is data in the receive buffer. After reading the SPI_DAT register, the hardware will clear this flag to 0.

16.3.3.3 **BUSY flag bit (BUSY)**

When the transmission starts, the hardware sets the SPI_STS.BUSY flag to 1, and after the transmission ends, the hardware clears the SPI_STS.BUSY flag to 0.

Only when the device is in the master one-wire bidirectional receive mode, the SPI_STS.BUSY flag will be set to 0 when the communication is on going.

The SPI_STS.BUSY flag will be cleared to 0 in the following cases:

- End of transmission (except for continuous communication in master mode);
- Turn off the SPI module (SPI_CTRL1.SPIEN=0);
- The master mode error occurs (SPI_STS.MODERR=1)

When the communication is discontinuous: the SPI_STS.BUSY flag is cleared to '0' between the transmission of each data item.

When communication is continuous: in master mode, the SPI_STS.BUSY flag remains high during the entire transfer process; In slave mode, the SPI_STS.BUSY flag will be low for 1 SPI clock cycle between each data item transfer. So do not use the SPI_STS.BUSY flag to handle the sending and receiving of each data item.

16.3.4 **Turn off the SPI**

In order to turn off the SPI module, different operation modes require different operation steps:

16.3.4.1 Master or slave full duplex mode

- 1. Wait for the SPI_STS.RNE flag to be set to 1 and the last byte to be received;
- 2. Wait for the SPI_STS.TE flag to be set to 1;
- 3. Wait for the SPI_STS.BUSY flag to be cleared to 0;
- 4. Turn off the SPI module (SPI_CTRL1.SPIEN=0).

16.3.4.2 **one-way send-only mode or bidirectional send mode for master or slave**

- 1. After writing the last byte to the SPI_DAT register, wait for the SPI_STS.TE flag to be set to 1;
- 2. Wait for the SPI_STS.BUSY flag to be cleared to 0;
- 3. Turn off the SPI module (SPI_CTRL1.SPIEN=0).

16.3.4.3 one-way receive-only mode or bidirectional receive mode for master

- 1. Wait for the penultimate SPI_STS.RNE to be set to 1;
- 2. Before closing the SPI module (SPI_CTRL1.SPIEN=0), wait for 1 SPI clock cycle (using software delay);
- 3. Wait for the last SPI_STS.RNE to be set before entering shutdown mode (or turning off the SPI module clock).

16.3.4.4 **one-way receive-only mode or bidirectional receive mode for slave**

- 1. The SPI module can be turned off at any time (SPI_CTRL1.SPIEN=0), and after the current transfer is over, the SPI module will be turned off;
- 2. If you want to enter the shutdown mode, you must wait for the SPI_STS.BUSY flag to be set to 0 before entering the shutdown mode (or turn off the SPI module clock).

16.3.5 Error flag

16.3.5.1 Master mode failure error (MODERR)

The following two conditions will cause the master mode failure error:

- NSS pin hardware management mode, the master device NSS pin is pulled low;
- NSS pin software management mode, the SPI_CTRL1.SSEL bit is set to 0.

When a master mode failure error occurs, the SPI_STS.MODERR bit is set to 1. An interrupt is generated if the user enables the corresponding interrupt (SPI_CTRL2.ERRINTEN=1). The SPI_CTRL1.SPIEN bit and SPI_CTRL1.MSEL bit will be write protected and both are cleared by hardware. SPI is turned off and forced into slave mode

Software performs a read or write operation to the SPI_STS register, and then writes to the SPI_CTRL1 register to clear the SPI_STS.MODERR bit (in multi-master mode, the master's NSS pin must be pulled high first).

Normally, the SPI_STS.MODERR bit of the slave cannot be set to 1. However, in a multi-master configuration, the

slave's SPI_STS.MODERR bit may be set to 1. In this case, the SPI_STS.MODERR bit indicates that there is a multimaster collision. The interrupt routine can perform a reset or return to the default state to recover from an error state.

16.3.5.2 **Overflow error (OVER)**

When the SPI_STS.RNE bit is set to 1, but there is still data sent into the receive buffer, an overflow error will occur. At this time, the overflow flag SPI_STS.OVER bit is set to 1. An interrupt is generated if the user enables the corresponding interrupt (SPI_CTRL2.ERRINTEN=1). All received data is lost, and the SPI_DAT register retains only previously unread data.

Read the SPI_DAT register and the SPI_STS register in turn to clear the SPI_STS.OVER bit.

16.3.6 SPI interrupt

Interrupt event	Event flag bit	Enable control bit		
Send buffer empty flag	TE	TEINTEN		
Receive buffer non empty flag	RNE	RNEINTEN		
Master mode failure event	MODERR			
Overflow error	OVER	ERRINTEN

rw	rw			rw	rw	rw	rw	rw	rw		rw		rw	rw	rw

Bit field	Name	Describe
15	BIDIRMODE	Bidirectional data mode enable
		0: Select the "two-wire one-way" mode.
		1: Select the "one-wire bidirectional" mode.
14	BIDIROEN	Output enable in bidirectional mode
		0: Output disable (receive-only mode).
		1: Output enabled (send-only mode).
		In master mode, the "one-wire" data line is the MOSI pin, and in slave mode, the "one-wire"
		data line is the MISO pin.
13:12	Reserved	Reserved, the reset value must be maintained.
11	DATFF	Data frame format
		0: 8-bit data frame format is used for sending/receiving.
		1: 16-bit data frame format is used for sending/receiving.
		Note: This bit can only be written when SPI is disabled (SPI_CTRL1.SPIEN=0), otherwise an
		error will occur.
10	RONLY	Only receive mode
		This bit, together with the SPI_CTRL1.BIDIRMODE bit, determines the transfer direction in
		two-wire one-way mode. In the application scenario of multiple slave devices, this bit is only set
		to 1 by the accessed slave device, and only the accessed slave device can output, so as to avoid
		data line conflicts.
		0: Full duplex (sending mode and receiving mode).
		1: Disable output (receive-only mode).
9	SSMEN	Software slave device management
		When the SPI_CTRL1.SSMEN bit is set to 1, the NSS pin level is determined by the value of
		the SPI_CTRL1.SSEL bit.
		0: Disable software slave device management.
		1: Enable software slave device management.
8	SSEL	Internal slave device selection
		This bit only has meaning when the SPI_CTRL1.SSMEN bit is set. It determines the NSS level,
		and I/O operations on the NSS pin have no effect.
7	LSBFF	Frame format
		0: Send MSB first.
		1: Send LSB first.
		Note: This bit cannot be changed during communication.
6	SPIEN	SPI enable
		0: Disable SPI device.
		1: Enable the SPI device.
		Note: When turning off the SPI device, please follow 16.3.4 Section's procedure operation.
5:3	BR[2:0]	Baud rate control
		000: fPCLK/2

Bit field	Name	Describe
		001: fPCLK/4
		010: fPCLK/8
		011: fPCLK/16
		100: fPCLK/32
		101: fPCLK/64
		110: fPCLK/128
		111: fPCLK/256
		Note: This bit cannot be changed during communication.
2	MSEL	Master device selection
		0: Configure as the slave device.
		1: Configure as the master device.
		Note: This bit cannot be changed during communication.
1	CLKPOL	Clock polarity
		0: In idle state, SCK remains low.
		1: In idle state, SCK remains high.
		Note: This bit cannot be changed during communication.
0	CLKPHA	Clock phase
		0: Data is sampled on the first clock edge.
		1: Data is sampled on the second clock edge.
		Note: This bit cannot be changed during communication.

Nanshan District, Shenzhen, 518057, P.R.China

16.4.5 SPI data register (SPI_DAT)

Address: 0x0C

Reset value: 0x0000

15											0
	1	1	1	ı ı	1		1	1	1	1	
					DAT[15:0]					
											.
					r	W					

Bit field	name	Describe
15:0	DAT[15:0]	Data register
		Data to be sent or received
		The data register corresponds to two buffers: one for write (send buffer); The other is for read
		(receive buffer). Write operation writes data to send buffer; The read operation will return the data in
		the receive buffer.
		Note on SPI mode: According to the selection of the data frame format by the SPI_CTRL1.DATFF
		bit, the data sending and receiving can be 8-bit or 16-bit. To ensure correct operation, the data
		frame format needs to be determined before enabling the SPI.
		For 8-bit data frame format: the buffer is 8-bit, and only SPI_DAT[7:0] is used when sending and
		receiving. When receiving, SPI_DAT[15:8] is forced to 0.
		For 16-bit data frame format: the buffer is 16-bit, and the entire data register is used when
		sending and receiving, that is, SPI_DAT[15:0].

17 Beeper

17.1 Introduction

The Beeper module supports complementary outputs and can generate periodic signals to drive external passive Beeper. Used to generate a prompt tone or an alarm sound.

17.2 Function description

Beeper as an independent module, is mounted on the APB bus, working clock source is LSI.

- Single or dual outputs can be configured
- Support two outputs to complement each other
- Output frequency can be configured: 1kHz, 2kHz, 4kHz, 8kHz

17.3 Beeper registers

These peripheral registers must be operated in word (32-bit) mode.

17.3.1 Beeper register overview

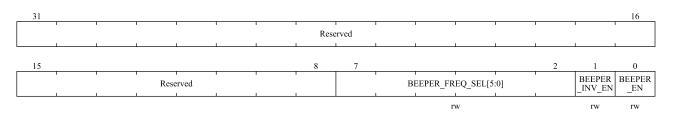

Table 17-1 Beeper register overview

18 Debug support (DBG)

18.1 Overview

N32G003 uses Cortex®-M0 core, which integrates hardware debugging module. Support instruction breakpoint (stop when instruction fetches value) and data breakpoint (stop when data access). When the core is stopped, the user can view the internal state of the core and the external state of the system. After the user's query operation is completed, the core and peripherals can be restored, and the corresponding program can continue to be executed.

The hardware debugging module of the N32G003 core can be used when it is connected to the debugger (when it is not disabled).

N32G003 supports the following debugging interfaces:

Serial wire interface

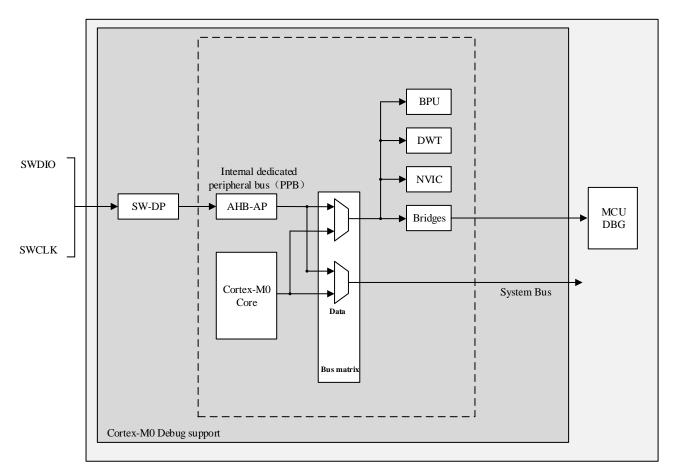

Figure 18-1 N32G003 level and Cortex®-M0 level debugging block diagram

ARM Cortex®-M0 core hardware debugging module can provide the following debugging functions:

- SW-DP: Serial wire debugging port
- AHB-AP: AHB access port
- BPU: Break point unit

DWT: Data watchpoint trigger

Reference:

- Cortex®-M0 Technical Reference Manual (TRM)
- ARM debug interface V5 structure specification
- ARM CoreSight development tool set (r1p0 version) technical reference manual

18.2 SWD function

The debugging tool can call the debugging function through the above-mentioned SWD debugging interface.

18.2.1 **Pin assignment**

SWD (serial debug) interface consists of two pins: SWCLK (clock pin) and SWDIO (data input and output pin).

The pin assignment of SWD debug interface is shown in the following table:

Debug port	Pin assignment
SWDIO	PA8
SWCLK	PA9

Table 25-1 Debug port pin

19 Unique device serial number (UID)

19.1 Introduction

MCU series products have two built-in unique device serial numbers with different lengths, namely 96-bit UID (Unique device ID) and 128-bit UCID (Unique Customer ID). These two device serial numbers are stored in the system configuration block of the flash memory, and the information is programmed during manufacture, and any MCU microcontroller is guaranteed to be unique under any circumstances. It can be read by user applications or external devices through CPU or SWD interface and cannot be modified.

UID is 96 bits, which is usually used as serial number or password. When writing flash memory, this unique identifier is combined with software encryption and decryption algorithm to further improve the security of code in flash memory.

UCID is 128 bits and complies with the definition of the Nations Technologies chip serial number. It contains information about chip production and version.

In addition to the above two device serial numbers, there is also a 32-bit DBGMCU_ID, which contains the chip version number, chip model, and Flash/SRAM capacity information.

19.2 UID register

Start address: 0x1FFF_F4FC, 96 bits in length.

19.3 UCID register

Start address: 0x1FFF_F4D0, 128 bits in length.

19.4 DBGMCU_ID register

Start address: 0x1FFF_F508, 32 bits in length.

For different bytes, the low byte comes first and the high byte follows; for the same byte, the high bit comes first and the low bit follows.

Description	Size	Remark
	4bit	The lower 4 bits of the chip version number.
Chip version number	4bit	The upper 4 bits of the chip version number.
	4bit	The upper 4 bits of the chip model.
		The Chip model consists of 12 high, middle and
Chip model		low bits
	4bit	The middle 4 bits of the chip model.
	4bit	The lower 4 bits of the chip model.
Elash sonasity	4bit	Flash capacity indicator.
Flash capacity		2KB as unit, FLASH size = N * 2KB

Table 19-1 DBGMCU_ID bit description

Nations Technologies Inc. Tel: +86-755-86309900 Email: info@nationstech.com Address: Nations Tower, #109 Baoshen Road, Hi-tech Park North. Nanshan District, Shenzhen, 518057, P.R.China

		Note: 0x8 indicates capacity16KB; 0xF indicates
		capacity 29.5KB
SDAM somesity	4bit	SRAM capacity indicator.
SRAM capacity		1KB as unit, SRAM size = N * 1KB
Reserved	4bit	Keep it all 1.

20 Version history

Date	Version	Remark
2022.10.10	V1.0	Initial release
2023.7.7	V1.1.0	 Section 5.2.5.4.2: PA9 adds UART2_RX multiplexing function Section 2.2.1.6: the option byte adds USER3[6] LVR reset enable bit and the corresponding FLASH_USER register read-only bit Table 2-5: modify SWD access rights for L1 level Table 19-1: modify Flash capacity note

21 Notice

This document is the exclusive property of Nations Technologies Inc. (Hereinafter referred to as NATIONS). This document, and the product of NATIONS described herein (Hereinafter referred to as the Product) are owned by NATIONS under the laws and treaties of the People's Republic of China and other applicable jurisdictions worldwide.

NATIONS does not grant any license under its patents, copyrights, trademarks, or other intellectual property rights. Names and brands of third party may be mentioned or referred thereto (if any) for identification purposes only.

NATIONS reserves the right to make changes, corrections, enhancements, modifications, and improvements to this document at any time without notice. Please contact NATIONS and obtain the latest version of this document before placing orders.

Although NATIONS has attempted to provide accurate and reliable information, NATIONS assumes no responsibility for the accuracy and reliability of this document.

It is the responsibility of the user of this document to properly design, program, and test the functionality and safety of any application made of this information and any resulting product. In no event shall NATIONS be liable for any direct, indirect, incidental, special, exemplary, or consequential damages arising in any way out of the use of this document or the Product.

NATIONS Products are neither intended nor warranted for usage in systems or equipment, any malfunction or failure of which may cause loss of human life, bodily injury or severe property damage. Such applications are deemed, "Insecure Usage".

Insecure usage includes, but is not limited to: equipment for surgical implementation, atomic energy control instruments, airplane or spaceship instruments, all types of safety devices, and other applications intended to support or sustain life.

All Insecure Usage shall be made at user's risk. User shall indemnify NATIONS and hold NATIONS harmless from and against all claims, costs, damages, and other liabilities, arising from or related to any customer's Insecure Usage.

Any express or implied warranty with regard to this document or the Product, including, but not limited to, the warranties of merchantability, fitness for a particular purpose and non-infringement are disclaimed to the fullest extent permitted by law.

Unless otherwise explicitly permitted by NATIONS, anyone may not use, duplicate, modify, transcribe or otherwise distribute this document for any purposes, in whole or in part.
